NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	**19s. 6d.**	**24s.**
Half-yearly (26 numbers)	**10s. 6d.**	**13s.**
Quarterly (13 numbers)	**5s. 6d.**	**7s.**

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."
Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.
Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

THE ALKALI REPORT.

THE annual reports of the chief inspectors under the Alkali Works Regulation Act are assuming an ever-increasing importance. From the outset they have been highly valued as reliable sources of statistical information on the British heavy chemical industry, but within recent years the considerable developments in the functions of the alkali inspectorate have contributed to make the reports documents of exceptional technical interest. The alkali inspectors and their staffs are indefatigable workers. Not content with acting as "technical policemen," they are ever ready to suggest means whereby offending works can so modify and adjust their processes as to bring them into satisfactory operation, even when such advice entails a good deal of experimental work on the part of the advisors themselves. The most recent activities of the inspectorate include the investigation of problems of fundamental interest to the industry as a whole. In last year's report the chief inspector described the work that had been done on the problem of the disposal of effluent spent liquors from the ammonia-distillation process. It may be remembered that the phenols were found to be largely responsible for the objectionable nature of the effluent, and that a method was devised whereby they could be eliminated to a great extent by blowing the liquors with boiler-fire gases under suitable conditions. An experimental plant has been erected at the Hornsey gasworks, and has been functioning continuously since February, 1921, decolourising and dephenolating the whole of the effluent liquors produced in the manufacture of 2½ to 3 tons of sulphate of ammonia per 24 hours. Although the percentage purification effected by this plant has not equalled the results obtained in the laboratory, yet it has been highly satisfactory, and further progress in the solution of the problem is now recorded. The treatment referred to above, whilst removing the bulk of the phenols, does not affect the thiocyanates and thiosulphates in the effluent, which, indeed, cannot be economically removed by any method of chemical treatment. Bacterial treatment in suitably prepared filter beds has, however, been investigated, and holds out high promise of success when applied to the dephenolated effluent. Filter beds are being erected for the purpose at Hornsey, and the practical results of the trials will be awaited with interest. In

556059

yet another direction have the alkali inspectorate been active. At the Cromwell House laboratories detailed experiments have been made on the pickling process in tinplate manufacture. The rather vague ideas that have hitherto been current regarding the restraining action of certain colloids on the pickling process have, as the result mainly of the work of Mr. H. J. Bailey, been replaced by concrete and fairly detailed knowledge, not only of the mechanism of the process, but of the relative merits of the various restrainers that have been proposed. Much of the data obtained in this investigation is already in the hands of tinplate manufacturers, and has led in many instances to considerable economies. So far as the general routine work of the alkali inspectors is concerned, there is little to comment upon. Contravention of the provisions of the Act by registered works has, on the whole, been negligible, both in England and Wales and in Scotland. The diminution of the number of works registered—from 1,283 in 1921 to 1,240 in 1922—is not perhaps so great as might have been expected in view of general trade conditions. It is interesting to note that the saltcake stage of the old Leblanc process is likely to be carried out for many years yet, the growing demand for sodium sulphide meaning a constant call for the sulphate.

LOWER PRICES FOR SULPHATE.

Contrary to the action of the producers of Chilean nitrate, makers of sulphate of ammonia in this country have reduced prices to a much lower level than those operating during the past year. The problems facing each of these industries differ considerably, but the much lower price of sulphate, calculated on the nitrogen content, is a factor which should influence for good the position of that material, both at home and in the world's markets. The lower cost of raw materials, principally acid, and certain other considerations affecting production, would certainly have permitted of some reduction being made in the price to the home consumer, though it would hardly have been thought possible to record so large a decrease. It is well known that the home consumer is obtaining cheap sulphate at the expense of our foreign customers, and the profits accruing from the excellent exportation of the past season are doubtlessly helping to compensate manufacturers. There is every reason why the domestic demand should be stimulated, for the Federation will have to meet a constantly increasing competition from American producers, and from the nitrate industry. Coincident with this competition is the heavy production in this country, consequent on the activity in the coking plants, and the promise of a supply of synthetic nitrate, amounting this year, in all probability, to about 50,000 tons. According to the Alkali Inspector's Report, production of sulphate from all sources in Great Britain reached over 350,000 tons in 1922, compared with 250,000 tons in the previous year. It is not too much to hope that low prices, combined with a high standard of excellence, will result in a widespread demand for sulphate of British manufacture.

A STANDARD CONTRACT FOR CHEMICALS.

Some six weeks ago, when discussing this subject, we mentioned that the Salesmen's Association of the American Chemical Industry was engaged in drawing up a standardised form of contract for chemicals. The task proved of considerable difficulty, and the criticisms of the Committee of the American Chemical Manufacturers' Association, who worked in co-operation with the Salesmen's Committee, necessitated the revision of the draft form four times. After three months' work, however, complete agreement has been arrived at, and we have now had the opportunity of studying the final report of the Joint Committee and the uniform contract note that is to be submitted to the American chemical industry. The latter is a particularly simple document, with only six items under the heading of "Terms and Conditions," and is evidently intended for American internal trade only. One of the main points upon which emphasis has been stressed in the report is the necessity for maintaining the principle of a fixed price as the only one compatible with absolute fairness between buyer and seller, and with ensuring stability in the chemical trade. Although many American chemical manufacturers possess highly complicated and individualised contract forms of their own, the Joint Committee states that practically all the leading companies are prepared to adopt a standardised contract. The proposed contract form does not contain an arbitration clause, but as the movement in favour of arbitration as a means of settling commercial disputes is at present making great headway in the United States, it is not improbable that such a clause may, in the near future, be inserted. If the project does prove successful in America, the British chemical industry will be unable to neglect the lesson, and the standardised contract introduced by the British Chemical Trade Association over three years ago should arouse wider practical interest than it has done in the past.

PATENT OFFICE PROCEDURE.

According to the President of the Chartered Institute of Patent Agents, a change is taking place in the routine of the Patent Office which is likely to prove prejudicial to the interests of many inventors in the chemical field. The question of whether an alleged invention contains good subject matter, or, in other words, involves sufficient inventive ingenuity to support a patent, has hitherto been one left to the law courts to determine. Within the last few months, however, it has been observed that examiners in the Patent Office are themselves claiming the right to reject patent applications if they consider there exists an insufficiency of subject matter—a claim unjustified by any change in the British Patent Acts. With regard to chemical inventions in particular, the examiners have not the necessary evidence before them to decide the point equitably, and the President of the Chartered Institute has proposed that the Institute of Chemistry should co-operate with the patent agents in protesting against this undesirable change in practice.

THE ALKALI INSPECTORS REPORTS.

SATISFACTORY OPERATING CONDITIONS DURING 1922.

THE reports of the alkali inspectors for England and Wales and for Scotland for the year 1922 have just been published. In his report, the chief inspector for England and Wales (Mr. T. Lewis Bailey) states that the total number of works registered was 1,240, which entailed the inspection of 2,005 separate units (processes). Compared with the previous year this is a reduction of 43 in the number of works, and of 64 in the number of processes.

Although there has been a distinct improvement in some sections of the heavy chemical trade, what may be called normal conditions have not yet been re-established. The introduction of new methods of manufacture is, however, a hopeful sign for the future of the country, and it calls for increased vigilance on the part of the alkali inspectors. This year again several works have been found, where operations, registrable under the Alkali, etc., Works Regulation Act, 1906, were being carried on without previous registration, viz.: 2 bisulphite works, 1 chemical fertiliser works, 1 salt works, and 2 tar distillation works. It seems strange that even yet it should be necessary to call the attention of chemical manufacturers to the penalties prescribed for such contravention of the Act.

The total number of inspections made during the year was 3,837, in the course of which 2,457 quantitative estimations of the noxious constituents of chimney and other gases escaping from the processes in operation, were made. Details as to the average amounts of gases escaping are given below:—

I.—Average Amounts of Acid Gases Escaping.

Expressed as Grains per Cubic Foot.

—	General Average.		
	1922.	1921.	1920.
1. *Muriatic Acid*:—			
Condensed in alkali works per cent.	98.6	98.5	98.5
In gases of chimney or final outlet:—			
(*a*) Alkali and copper (wet process) works	0.069	0.073	0.088
(*b*) Salt works	0.044	0.040	0.061
2. *Acidities of Chimney and Other Gases in terms of* SO_3:—			
Escaping from sulphuric acid chambers	1.22	1.06	1.13
Final outlets from sulphuric acid concentration processes	0.65	0.68	0.71
Chimneys of smelting works	3.17	1.73	2.34
Chimneys of other works	0.70	0.66	0.73
All chimneys	1.00	0.75	0.95
3. *Condensers of Chemical Manure Works*: (SO_3 equivalent of H_2SiF_6)	0.08	0.06	0.09

A considerable number of visits were paid to unregistered works, concerning which complaints had been received from local authorities or from individuals. In practically all instances it was ascertained that the complaints were not due to emission of noxious or offensive vapours from registrable processes, but from operations concerning which the alkali inspector has no jurisdiction. Registered operations, on the whole, have been conducted satisfactorily. Complaints of a serious character have been few, and in all cases prompt remedial measures were adopted. Two works in particular, however, have given considerable trouble, but a steady application of pressure has secured better working and greater attention to detail, with the result that much improvement has been effected in the atmospheric condition of the neighbourhood of the works in question. It is confidently anticipated that the improvement is of a permanent character.

Alkali and Copper (Wet Process) Works.

A considerable amount of salt-cake continues to be made; large quantities are employed for the production of sodium sulphide, a manufacture which has extended considerably of late years; heavy consignments, too, have been used in the wood pulp industry. It is a logical sequence of the disappearance of the older alkali process that the synthetic manufacture of hydrochloric acid from chlorine and hydrogen, obtained by electrolysis of brine, is showing signs of extending. During the past year, however, the acid position has been easy, owing to idleness in the fibre separation trade, which trade is usually responsible for a fairly large consumption of hydrochloric acid. The employment of gas firing in connection with salt-cake furnaces has unfortunately shown no progress as yet.

The district inspector had occasion to complain of the conditions prevailing at one alkali works, where exits generally were so near the statutory limit that occasional excessive escapes became inevitable. The repacking of one of the towers proved to be necessary: moreover, it was considered necessary to ask for additional condensing plant, and this has been provided; the method of working the final scrubbers has been altered also. As a result a considerable improvement has been effected. Apart from this instance of inefficiency, there has been little difficulty with works of this class, occasional temporary disorganisation only occurring at several works. Percentage condensation has been quite good, and exits have been satisfactory.

Cement Works.

The most serious nuisance that is likely to occur at these works is due to dust. Good depositing chambers are usually sufficient to obviate any serious trouble, but much more satisfactory is a system of filtration, such as is attained by passing the dust-laden gases through bags of suitable material. At one works, where dust trouble has been particularly acute, a good bag-house has effected the collection of many tons of dust weekly and at the same time an almost entire cessation of the nuisance. Any reduction in fuel consumption is, of course, financially beneficial to the manufacturer, and at the same time it improves atmospheric conditions in the immediate surroundings of the works, and so improvements in vertical kilns with this end in view are welcome. It would appear that the introduction of a rotating grate has given encouraging results—whether the patentee's claim of a 50 per cent. reduction is substantiated remains to be seen.

Smelting Works.

The deposition of dust from smelting-furnace gases continues to receive attention; cooling is a very efficient aid to the deposition of flue dust, and more use might be made of this—draught conditions do not necessarily form an insuperable barrier. In connection with the electrostatic removal of dust from furnace gases more attention is necessary to humidity than is usually given. The highest acidities of chimney gases are usually obtained in the calcination of zinc blende, and the problem of dealing with these gases is receiving at our hands such attention that one may look for further improvement at no very distant date. Mechanical calciners are somewhat handicapped by the amount of lead contained in the concentrates so largely imported into this country. The essential difficulties are twofold: (*a*) the production of a partially calcined product of a resistant nature, which gives trouble with the mechanical rabbles, causing breakage of parts; and (*b*) insufficient removal of sulphur unless a high-temperature final roast is included in the operation. Furthermore, if the calciner gases are employed in the manufacture of sulphuric acid, volatilised lead compounds are apt to cause considerable trouble in the Glover towers, where they collect and form obstructions.

Experiments are in progress, however, with a view to simplifying the method of procedure. It is hoped that we are on the way to superseding such methods of calcining blende as are not accompanied by conversion of the sulphur gases into sulphuric acid. Hitherto either the low sulphur-dioxide content of the gases from many smelting operations, or the very variable composition of such gases, has precluded any idea of satisfactorily and economically converting the sulphur constituents into sulphuric acid. Reference to the averages table, given above, shows that the gases of smelting works chimneys have a much higher acidity than all others; and this becomes more marked as the activity of blende calcination works increases.

Sulphuric-acid Works.

The outstanding feature has been the rapid extension of the use of sulphur, from which now quite an appreciable proportion of the acid of the country is being produced. At several works rotary sulphur burners have been in successful operation. Electrostatic deposition of dust from burner gas is receiving more attention, but one feels constrained to remark that each case should receive special consideration according to the nature of the material to be deposited. Concerning lead chamber systems there is little that calls

for remark. Leakage of sulphur dioxide at the point of entry of the burner pipe into the Glover tower is frequently a cause of annoyance to both inspectors and works managers; a water-jacketed collar, burnt on to the side of the tower, has been used for some time at one works with great advantage. Plant has been kept generally in good condition, and exists, with one or two exceptions, have been very satisfactory. The average of tests made at all the sulphuric-acid (class II.) works is satisfactorily low; there has been a steady reduction each year since 1917. One works has caused some anxiety during several months of the year, complaints of excessive emission of acid fumes being received on two occasions. At this works sulphuric acid is concentrated in glass bottles, and it transpired that on both occasions there had been breakage of several bottles, which were almost new. These bottles proved to be heavier, and consequently thicker, than those hitherto employed; they were, therefore, less able to withstand such temperature variations as might occur at periods of stoking. A strong letter of warning was sent to the owner of the works, who promptly removed all the bottles of the type which had been responsible for the trouble; since that was done, no similar occurrence has been reported. The Calder-Fox scrubber has been further modified in detail, and the need for the introduction of a damper before the scrubber has been obviated. The results recorded during operation of this newer type have been very gratifying.

With regard to contact processes, some improvement is to be chronicled in the working of Grillo plants, but more is needed. At the outset dust, and subsequently acid mist, are essentially to be guarded against, if conversion efficiency is to be maintained. In each case electrostatic deposition can play a very important part in attaining the end desired. Attention has been drawn to this in previous years, and it is gratifying to report that this year such means have been introduced at one works with apparently excellent results. At one installation exit gases are to be scrubbed with a solution of sodium carbonate, with resulting production of bisulphite. It should not, however, be necessary to have recourse to any such means of recovery simply for the purpose of bringing the acidity of the exit gases within reasonable limits.

Fertiliser Works.

The average acidity of gases from the condensers at these works has now for three years been under 0.1 grain per cub. ft., reckoned as the SO_3 equivalent of hydrofluosilicic acid. It must be understood that this figure by itself is insufficient as an indication of the efficiency of any one plant; percentage removal of gases must be taken into account, and this runs to a figure usually approaching 98 per cent. and frequently 99 per cent. I would remind manufacturers of the remarks made in last year's report concerning the designing of scrubbing plant. During the year just ended considerable trouble has been given by several newly-erected plants for which the scrubbing system had been quite badly designed. Tower space must be ample and fan speed must not be excessive. In several instances during the past year it has been necessary to ask for a reduction of fan speed, and in each case, where such reduction has been effected, the result has been satisfactory in all respects. The introduction of excessive volumes of cold air into the system is neither necessary nor desirable. Mr. Sutton, in his district report, states that further experience of the use of high-pressure water sprays confirms the advantage of this method of scrubbing as compared with the old shower-and-drip method.

Sulphate-of-Ammonia and Gas-liquor Works.

The outstanding feature at present is the general tendency towards the production of neutral sulphate. This is usually effected by neutralising the fished acid salt and then drying, but an interesting departure from this method is the "Bedford" process, in which a primary and a secondary saturator are employed, the liquor in the main (primary) saturator being taken to neutrality, so that the salt, as fished, is already neutral and requires drying only.

It is not edifying in these days of scientific control to reflect on the somewhat haphazard methods prevailing in so many sulphate-of-ammonia works; by-products ought surely to be manufactured under as economical conditions as possible, compatible with quality of the article produced. the whole process of the treatment of ammoniacal liquor seems to be worthy of more attention at the hands of manufacturers than it receives; but two points in particular are worthy of special consideration—first, on the ground of economy and secondly, by reason of the present-day difficulty, so frequently experienced, of getting rid of spent liquors. I refer here to the quantities of lime and steam used in the still: the one is a case of the amount of alkali actually required to bring about the setting free of the "fixed" ammonia, the other is a question of the heat units required in the distillation process. It is a fact that these two items show very great variations, and both are frequently in far greater excess than there is any need for. These points are considered in some detail in that portion of the present report which deals with effluent spent liquors.

II.—Amount of Ammonia Products Manufactured in England and Wales, 1922.

Expressed as Sulphate (25¾ per cent. NH_3)—Tons.

From Liquor Produced in—	1922.	1921.	1920.
Gasworks	144,817	129,431	143,979
Iron works	83	167	718
Shale works	—	—	—
Coke oven works	125,679	54,184	143,391
Producer-gas and carbonising works (bone and coal)	4,722	4,446	10,005
Total	275,301	188,228	298,093

Chlorine and Hydrochloric Acid Works.

The production of liquid chlorine has simplified the manufacture of chlorine compounds by doing away with the older and less convenient methods, which entailed the making of chlorine on the spot, and consequently users of chlorine are on the increase. In every instance plants have been operated satisfactorily and precautions have been taken to prevent escape of chlorine into the atmosphere.

The conditions existing at tinplate flux works in the previous year have been more than maintained this year, and chimney exits have been highly satisfactory. Work of an investigatory character has been commenced this year with a view to further improving general conditions. Now that scruff treatment methods have so far advanced as to render the neighbourhood of tinplate works reasonably free from any annoyance due to noxious vapour, the point of attack has been shifted to an earlier stage of the tinplate operations, with a view to improving the pickling process and to ascertaining how far such may affect the character and quantity of the scruff; this, it is hoped, may lead to still further improvement of the atmospheric surroundings of the works. The laboratory work carried out thus far has given excellent results, so far as details of the pickling process are concerned, and Mr. H. J. Bailey's assiduity at the works themselves has had the effect of inducing the tinplate manufacturers to consider important points which have been ignored in the past. (The work referred to is summarised later in a special section of the report.)

Sulphide Works.

A number of complaints were received, alleging emission of sulphuretted hydrogen from new processes, which are not registrable under the Act. This gas is both unpleasant and noxious. There should be no serious difficulty in preventing its getting into the air from any process that has so far come under notice. Sulphuretted hydrogen is easily removable by absorption, using such materials as hydrated oxide of iron or slaked lime. These may be used either in what may be termed a dry state or suspended in water, and, where considerable quantities of the gas have to be dealt with, it is quite possible to recover sulphur from the absorbent directly. The latter point is worthy of more consideration than is usually accorded to it. No sulphide works registered under the Alkali Act has given rise to complaint this year, although inspectors have found it necessary to take exception to a lack of adequate supervision in regard to sulphuretted-hydrogen escape from several works of other classes, viz.: sulphate-of-ammonia works and tar works.

Tar Works.

The most recent innovation in tar distillation is the use of a molten metallic alloy for heat transference in the still.

In each section of the plant the tar is fed in below the surface of a molten lead alloy, maintained at the desired temperature. Successful development of this variation from the usual plan of direct heating of the tar may have quite a number of advantages, including prevention of the separation of carbon. Practically the only cause of complaint this year has been due to want of attention to pitch coolers at some works. Leaky pitch coolers are a distinct source of nuisance in the neighbourhood of the works, and it has been necessary in a number of instances to require either immediate repair or entire renewal of faulty pitch coolers. Fume pipes from pitch coolers, too, are frequently neglected. There is no difficulty in providing and maintaining in good order a pipe from the top of the pitch cooler to ground level, which is lightly sealed in oil or even water. Other methods are in use, but that just mentioned is perfectly simple and quite efficacious. Neglect permitted in the matter of details in manufacturing operations leads inevitably to neglect regarding even more important points, and this in turn leads to general inefficiency both of plant and worker.

III.—Amount of Tar Products Manufactured in England and Wales, 1922.

—	Gas and Coke Oven Works.	Other Works.
	Tons.	Tons.
Tar distilled	1,176,610	9,384
Pitch produced	448,595	4,288

Where serious corrosion of the still is experienced, owing to the presence of tarry emulsions of an acid character, it is possible that considerable advantage may be obtained by the use of aluminium oleate, which may be prepared from oleic acid and such an aluminous material as alumino-ferric. This has been used at one works with considerable success.

The next section of the report is an account of the continuation of the experimental work on the problem of disposing of the effluent spent liquors from the ammonia distillation process as carried on at gasworks and coke-oven works. An abstract of this section of the report will appear in our next issue.

Then follows a very detailed account of the work carried on by the alkali inspectorate on the chemistry and technology of the pickling process in the manufacture of tin-plate. An account of this will also appear in an early issue.

The Alkali Regulation Act in Scotland.

Mr. J. W. Young, in his report to the Scottish Board of Health on the working of the Alkali, etc., Works Regulation Act, 1906, in Scotland during 1922, states that the number of works registered was 165, in which were operated 315 scheduled processes as follows:—6 alkali (saltcake), 1 alkali (wet copper), 1 cement, 2 smelting, 20 sulphuric acid, 16 sulphuric acid (Class II.), 27 chemical fertiliser, 14 gas liquor, 7 nitric acid, 111 sulphate and muriate of ammonia, 2 chlorine, 3 muriatic acid, 14 sulphide, 1 alkali waste, 11 lead deposit, 1 arsenic, 6 nitrate and chloride of iron, 1 carbon bisulphide, 5 paraffin oil, 7 bisulphite, 58 tar, and 1 zinc extraction. I made 511 visits to these works, and 27 to others not on the register. There were 295 chemical tests, in one of which acidity was measured exceeding the limit prescribed by the Act. Generally operations continued to be restricted, but during later months in some branches there was increased activity. No legal proceedings were taken under the Act.

Vegetation in neighbourhood of a sulphuric acid works was injured severely. There were novel features in the construction of chemical plant, raw material differed from previous supplies, and the management lacked experience to overcome these difficulties. In result acid gas, which should have been manufactured into sulphuric acid, escaped at times freely into the atmosphere. I was visiting as usual, but saw and heard nothing of these outbursts. Inspectors can best perform their duties when incidents occurring between their visits are communicated to them and their advice if necessary, sought. Several changes have been made, so that there is reason to expect lasting improvement.

By the courtesy of manufacturers, I am able to present the usual summary of raw materials and of products.

Alkali Works.

No salt was converted into alkali, and less than usual into saltcake; although demand for the latter from abroad improved. Conditions were good throughout at the works, and also at deposits of alkali waste. An old landmark, the great chimney of St. Rollox, has gone. Through distrust of its stability, demolition was in progress, but the shortened stem collapsed spontaneously, causing the loss of four lives. The general average amount of muriatic acid discharged into the air was in each cub. foot of chimney gases, 0.055 grain, the highest and lowest averages for any one work being 0.164 and 0.02 respectively. In no test was measured an amount of acid exceeding the Act limit of 0.2 grain.

—		1922.	1921.
		Tons.	Tons.
Pyrites and spent oxide burned		97,919	71,416
Phosphates and bones dissolved		69,301	51,796
Salts of ammonia (expressed as pure sulphate):—			
From gasworks	19,046		
,, iron works	2,996		
,, shale works	15,860		
,, coke, producer gas and carbonising works	7,939		
		75,841	62,343
Tar distilled:—			
At gasworks and coke ovens	138,385		
,, other works	34,786		
		173,171	148,608
Pitch produced:—			
At gasworks and coke ovens	41,978		
,, other works	19,375		
		61,353	58,833

Sulphuric Acid Works.

Spent oxide has been burned in greater quantity; inadequate retention of dust has caused frequent trouble. Unavoidable diminution of chimney draught caused a short period of disorganisation at one works, so that my test of the exit gases from the plant slightly exceeded the statutory limit of 4 grains of acidity. Processes comprised in Class II. have been rather busier than in 1921 and without incident. The general average acidity in each cub. foot of residual gases discharged was 0.59 grain of sulphuric anhydride; the highest and lowest from any one work were 2.29 and 0.22 respectively.

Chemical Fertiliser Works.

Good results of an improved system of condensation of the corrosive gases emanating from this process were mentioned in last year's report, and have continued. These are so destructive to the steel and ironwork of the modern type of den that repair or even renewal is needed in a few years. Some time ago I had suggested at one such works that the old-fashioned paint of slaked lime mixed with skim milk would surpass any oil paint in durability of coating and protective action towards the metal it covered. The manager has informed me that his trial was entirely satisfactory; his experience may be useful elsewhere. At another works, lately installing new plant, an irritating back rush of gas was noticed from the charging hole, although all was apparently in good order. Explanation was simple; the makers' designs were at fault. So long as mineral containing little carbonate was used, dissolving was easy; but with change to another material, richer in carbonate, reaction in the mixer was so vigorous that the charge overflowing into the flue choked the passage of gas to the wash-tower. The general average of the total acidity in each cub. foot of gases escaping finally was 0.09, expressed as the SO_3 equivalent of silico fluoric acid; the percentage condensation varied from 94 to 100.

Sulphate and Muriate of Ammonia and Gas Liquor Works.

At some works it was thought advantageous to run gas liquor to waste rather than to recover the contained ammonia. A few instances of leaking joints were observed in saturators; on my complaint they were quickly repaired. Drying of neutralised salt tends to be over elaborated and at too high a temperature, so that afterwards it is necessary to crush down or grind the lumps. None is so effective as the simpler plants, wherein an ample and steady current of warm air is led through the agitated salt. It is seldom necessary now to comment on oxide purifiers as kept too long in use. At the coke ovens of the Plean Colliery Company, near Stirling, fluorine is found in the gas liquor as a regular constituent. By reason of its corrosive properties on metal it is thought advantageous to remove it before recovering the dissolved ammonia. I am not aware that such presence of fluorine has been previously observed.

SAFEGUARDING OF INDUSTRIES ACT.

COMPLAINT AS TO FORMALDEHYDE UNDER PART I.*

THE further hearing of the application for the removal of formaldehyde from the Board of Trade List took place at the offices of the Board of Trade on Thursday and Friday, June 28 and 29, and was then adjourned until Monday, July 2. On June 28 the whole of the proceedings were private, evidence being given on behalf of Synthite, Ltd., with regard to their particular process of making formaldehyde. Such importance did Sir Arthur Colefax, K.C., attach to this evidence being *in camera* that even all the witnesses of this firm who were not actually required to give evidence as to the process were excluded from the room, as also was the official shorthand writer.

Evidence of Dr. Ormandy on Oxidation Syntheses.

On Friday, June 29, when the proceedings were resumed in public, there was some cross-examination of the evidence previously given *in camera*, but this cross-examination was on general lines, and did not disclose the details of the process. Dr. Ormandy, who had given evidence the previous day, was cross-examined by Mr. Swan, for the complainants, and said that the plant had either to be worked continuously night and day or completely closed down. On the subject of what constitutes a real synthesis, Dr. Ormandy's view was that formaldehyde, as manufactured from the products of the distillation of wood, is a synthetic product. He considered the process of converting methyl alcohol into formaldehyde, *per se*, a synthesis. He agreed it was a degradation, but only in the sense that it was used in thermodynamics, which had nothing to do with chemistry. The sense in which it had been put forward in this case was a common mis-use of the term degradation. His view was that if the chemical re-action was controlled then the process was synthetic.

Cross-examined with regard to oxidation as a synthetic step, Dr. Ormandy said that only when the step was a controlled oxidation, resulting in the production of another body which they desired to get, was it a synthetic step. Mere oxidation without any conditions whatever was not a synthesis; otherwise the burning of coal would be synthetic. He could not give a better illustration of controlled oxidation than the conversion of methyl alcohol into formaldehyde.

A discussion then took place as to the various methods mentioned in Richter for forming acetic acid, in which a differentiation was made between synthetic methods and other methods. Dr. Ormandy said that Richter nearly always dealt with nuclear synthesis, and arguments based on multi-carbon bodies seemed to him quite irrelevant in regard to the case of formaldehyde. Moreover, he did not by any means accept Richter as a man to be blindly followed.

Dr. Ormandy was again questioned by the Referee, and said he drew a distinction between the scientific and commercial meaning of synthesis. If he brought carbon dioxide and hydrogen over a catalyst, and actually isolated methane, he contended he would be entitled to say scientifically that it had been synthesised, but from the commercial point of view it was not a synthesis of a substance which could be produced in any quantity. It was, therefore, necessary to distinguish between a synthesis carried out commercially and one which was merely a scientific possibility. The process which had been described to the Referee *in camera* was so far from being automatic that if the operations were not watched most carefully, it would all go wrong. He agreed with Sir Arthur Colefax, from his knowledge of the process in Germany, that the product was usually water-white, unless there had been an accident in manufacture.

Mr. S. A. Brashier, a director of the firm of Walter H. Brown and Co., Ltd., chemical merchants, of London, gave evidence from the trade point of view, and said that during his many years' experience of the trade, formaldehyde had always been regarded and traded in, as a fine chemical. Of the sales of his firm of formaldehyde, 95 per cent. were used for disinfectant purposes. Cross-examined, Mr. Brashier said his firm dealt mainly with pitch and coal-tar derivatives, and had only been dealing with formaldehyde since the war, and he imported the material he had been selling.

The Referee asked whether his firm would expect formaldehyde to be water-white and free from impurities, even when this was not specified; and witness replied that he would. This concluded the evidence, and Counsel made their respective speeches.

Summing-up by Sir Arthur Colefax.

Sir Arthur Colefax, for the opponents, submitted that formaldehyde was rightly included in the list on three grounds—(1), that it is an analytical re-agent; (2) that it is a fine chemical; and, (3), that it is a synthetic organic chemical. In regard to the first, there was no question, on the evidence, that it was an analytical re-agent. He agreed that its use for this purpose was extremely small, and he did not wish to overstate his case in this respect. On the second point, he submitted that no case had been made in favour of formaldehyde not being a fine chemical. Formaldehyde was largely included under the heading of "Industrial Chemicals" because it had admittedly a very large industrial use, and he did not distinguish between its industrial uses. It was used as a disinfectant, and it had a much larger use for that purpose than the complainants had any conception of. He was not going to put formaldehyde forward as a pharmaceutical chemical, but such use as formaldehyde had in pharmacy, at any rate, was quite consistent with its being a fine chemical. The fact that formaldehyde was listed under "industrial" chemicals did not decide the point whether it was heavy or fine. Discussing the factors which made it a fine chemical he put, first and foremost, its extraordinary purity; it was not that it happened to be pure, but it was demanded pure, and only that which was pure had a normal sale. It was a fact that the material which was sold was of B.P. quality, both here and in the United States. It was incredible that the manufacturers would strive to produce this extremely pure substance for sale if it were not demanded.

The Decision Should not Depend Upon the "Synthetic" Point.

With regard to the process of manufacture: this was a very important matter. The Act was not cut to protect a particular body simply because it happened to be that body; it was out to protect British industry, and, therefore, essentially this question of manufacture must lie at the root of the definition of a fine chemical. Evidence had been given by everyone—and, he believed, he had called all the manufacturers, and they had all said the same thing—that this was a process of a most delicate character. It could go wrong within the brief space of a few minutes, and could end, in fact, in an explosion. Continuous control must be exercised, and the purpose of the skilled chemical control given to it was to guard against the process going wrong, and the consequences. Here was a process which could not possibly be conducted without *continuous* chemical supervision, and it was perfectly obvious, from the evidence, that the bulk of the cost was in respect of skilled chemical supervision. Counsel was most anxious that no decision should be given on this synthetic organic chemical point which, in his submission, would be seriously wrong. He, however, submitted definitely that this was a synthetic organic chemical, and he was particularly anxious to persuade the referee not to give any decision which would in any way conflict with its being such. Richter alone had defined "synthesis," and he had defined it in words which he (Sir Arthur) had always adopted. He repeated the definition:—"By the synthesis of a carbon derivative is understood its formation from the elements, or from such carbon derivatives which can be obtained from the elements." Sir Arthur said he had never sought to extend "synthesis" beyond that, and it fitted this case absolutely. Thorpe's definition was wider than Richter's. It was stated by Thorpe that, in its widest sense, the term "synthesis" meant the building up of carbon compounds either from their constituent elements or from groups of differently constituted molecules. Sir Arthur suggested that the difference between Richter and Thorpe was that Richter was definite and Thorpe was not. It was perfectly clear that the attempted use of Thorpe, that it was a *sine qua non* of synthesis that they should have a successive building up in the sense that they added brick to brick, was wrong, and it was not the way in which Thorpe used the term. After referring in detail to Mr. Parry's evidence, which, he said, he could not make head or tail of, and after referring to the definition of a synthetic organic chemical which was given in a United States Treasury Minute, for Customs purposes (which absolutely fitted this case), he said the point was that if they had a body which was

* For the previous hearings of this case see *The Chemical Trade Journal and Chemical Engineer*, June 22 (page 756) and June 29 (page 785).

naturally-occurring, and they passed from that to another body of a different molecular constitution by a chemical step, they had got a synthesis, provided that the natural body was one which could be synthesised.

On the afternoon of Monday, July 2, the final stage of the hearing was reached, and Mr. Kenneth Swan summed up on behalf of the Chemical Merchants' and Users' National Vigilance Committee.

The Delay in Hearing the Case.

Mr. Swan referred, first, to the delay which had occurred in the hearing of these cases. If formaldehyde were wrongly in the list, he said, the community had been losing, assuming importation to be about 1,800 tons, something like £20,000 per annum. It was clearly against the interests of the manufacturers to move in the matter at all, but counsel suggested that no blame could be attached to the importers for not actually bringing this case on. The fault lay in having the article in the list, if it were wrognly included. The importers could not be blamed for not rushing immediately into this enormous expense before they could see what they had to meet.

The Referee said that when he had raised this matter he was thinking not so much of this particular case as of the 350 or so articles in respect of which complaints had been made but no step had been taken. He was not suggesting ill faith anywhere, but they saw where it led; people might give notice of objection to hundreds of these things, but would not proceed, so that rival manufacturers would hesitate to manufacture these substances because in the end they might be taken out of the list. He considered that the position ought to be made clear.

Mr. Swan agreed that it was in the public interest that these cases should be brought on as rapidly as possible, but it could not be expected that an individual importer would incur this huge expense hurriedly. The Referee said there was no need to incur this large expense. The parties might easily come themselves (without counsel), and they should stick to the chemical under discussion. Mr. Swan asked whether the Board of Trade would instruct counsel in that case. The Referee replied that they would not; they had always said they would not. Mr. Ronca (Board of Trade) confirmed this. Mr. Swan pointed out that the Referee could not prevent the opponents from instructing counsel. The Referee said he thought he could, but he was not quite sure; he doubted very much whether opponents would get permission to be represented by counsel if the complainants and the Board of Trade were not instructing counsel.

Summing-up by Mr. Swan.

Mr. Swan then dealt with the question of synthesis in connection with formaldehyde. Sir Arthur Colefax had based his arguments upon grounds which were entirely different from those which Dr. Ormandy had adopted. There were the two divergent views, and they were to some extent contradictory. Sir Arthur Colefax's argument was that, because formaldehyde was a derivative of a body which could be synthesised, it was, therefore, a synthetic organic chemical. Dr. Ormandy had said that formaldehyde was a synthetic body, because the oxidation of the methyl alcohol was a synthetic reaction; that transition from methyl alcohol to formaldehyde, *per se,* was a synthetic reaction, and it was that which made formaldehyde a synthetic chemical.

The Referee said that Dr. Ormandy did not mean that the step from methyl alcohol to formaldehyde was synthetic, unless the raw material could be synthesised. Mr. Swan maintained that Dr. Ormandy was in direct conflict with Sir Arthur Colefax, and referred to the questions he himself had put to Dr. Ormandy in cross-examination

After some argument and denial on the part of the other side, Mr. Swan said the point he wanted to make out was that Sir Arthur's argument was based upon the statement that because it was a derivative of a body which could be synthesised, *ergo* it was a synthetic chemical. Dr. Ormandy, on the other hand, had based his view on the contention that the oxidation step was synthetic. This view, if accepted, would involve a recantation of the referee's decision in the camphor case, in which this question of degradation or decomposition was dealt with. His (Mr. Swan's) case was based upon Thorpe's definition and upon Richter's definition; he submitted that the two were absolutely consistent, and he had no qualification or alteration to suggest.

The Referee said that if the step from methyl alcohol to formaldehyde was not synthetic, and if they were using methyl alcohol which everybody agreed had not been obtained synthetically, he could not quite see how the formaldehyde could be synthetic in that case; yet, if Richter's definition were grammatically interpreted, it was. Mr. Swan said the confusion was due to the contention that because a thing could be synthesised it was necessarily a synthetic product. Sir Arthur had said that the method of production did not affect the question, and that was the root of his case. In the camphor case, for instance, it was held that because camphor could be synthesised it was synthetic. To say that because a chemical had been synthesised, or could be synthesised, that chemical was synthetic whether actually synthesised or not, involved them in the most utter contradiction. The Referee, after further discussion, said he understood Mr. Swan's case was that if the final step were a synthetic step, then formaldehyde was a synthetic body, whether synthetic methyl alcohol had been used or not. Mr. Swan agreed, and said that that was why he attached so much importance to Dr. Ormandy's evidence.

Another consideration which supported his view was that in the only two cases before the Referee in which synthesis had been considered, namely, the camphor and oxalic acid cases, the referee had considered the *de facto* method of production. In the camphor case each step was examined categorically to see whether it was in fact a synthetic step, and the conclusion come to was that, because there was a leap in the dark at one portion, there was no *de facto* synthesis. In the oxalic acid case, although he (Mr. Swan) had pressed the view that there was a leap in the dark there also, the referee had not accepted it, and had held that there was a *de facto* synthesis. He submitted that the referee could not come to any other conclusion than that formaldehyde made from methyl alcohol was not synthetic, unless Dr. Ormandy's view, that the oxidation process was a synthetic step, *per se,* were adopted. If Dr. Ormandy were right, then he (Mr. Swan) failed absolutely; but he submitted, with great confidence, that the referee must come to the conclusion that he was wrong.

The Referee, referring to his decision in the camphor case as to the meaning of "synthesis," said that one got into a great deal of difficulty in these cases. There was a restricted view and also a wider view. He would not be obstinate and adhere to a view in one case which had been accepted in another if he thought it should be reconsidered; he could only decide these things on the evidence.

Finally, Mr. Swan said that where they had a breaking down referred to in Richter as a synthesis, they would find that it was, in every instance, the last stage of a synthetic operation, and Mr. Parry had admitted that, where they had such breaking down as the last stage, it did not prevent a product being synthetic if there had been an aggregation of synthetic steps.

Should the Referee Concern Himself with Academic or Manufacturing Points?

On the fine chemical point Mr. Swan said he had a very definite submission to make. It was that the Act was intended to put a tax only upon what the trade regarded as fine chemicals, and, in appointing a referee instead of a body of expert chemists to adjudicate on questions in doubt, the Legislature had contemplated that the question involved was not really a chemical question. If there were no trade usage to show how a chemical was regarded, the referee was not asked to go further and classify that chemical, because that involved going into a maze of intricate chemical questions, and no one but a panel of chemists could decide it. Mr. Swan submitted he had established a very strong case that formaldehyde had never been treated by the trade as a fine chemical. The Referee said that the more one knew of the trade the more one saw how little the trade had used this expression "fine."

Mr. Trevor Watson pointed out that the Act did not say whether the referee was to be a barrister, a chemist, or anything else. The Referee said that if the Act had stated that the referee must know nothing about chemistry he would appreciate the point. He also asked what would be the position if he thought it ought to be classified as a fine chemical; and that, had the trade understood all about it, they would have classified it as a fine chemical. Mr. Swan suggested that the referee should never get into that frame of mind, because it was inferential, and was, therefore, irrelevant.

The Referee said he had never been so impressed as he had been in this case with the feeling that the people who decided upon trade usage knew very little about the chemical as to whether it was heavy or fine. They had no

idea how it was made, and yet they were the people who determined the classification. He had never felt so impressed with the feeling that it ought to be regarded as a fine chemical, and those who had said it was not were all wrong. Mr. Swan pointed out that in the tartaric-acid case the importers had got the manufacturers over from abroad in order to show how simple the manufacture was. In this case, however, his clients had not been able to go to that expense, and the referee had had an *ex parte* view as to the method of manufacture. He thought that probably that would account for the state of mind in which the referee found himself when he said he felt it ought to be classified as a fine chemical. If, on trade evidence, it was established that it was not considered a fine chemical, then it should go out of the list. The Referee considered that Mr. Swan's negative proposition was perfectly sound.

Mr. Swan said that there were three publications in which formaldehyde was referred to as definitely heavy; there were others in which it was distinguished from fine chemicals; there were others in which formaldehyde was included under the heading of "general," "technical," or "industrial," where these were distinguished from "pharmaceutical"; and there were still other publications in which formaldehyde was classified with other chemicals wholly or substantially heavy. That was a substantial body of trade evidence. All the direct trade evidence given pointed to formaldehyde not being treated as a fine chemical. On the question of the supervision required, Mr. Swan said that the evidence given on this had all the vice of *ex parte* evidence, because it was taken *in camera*, and was uncriticised by his experts. He contended that the object of the supervision was to get maximum yield, to avoid waste, and to extract every ounce possible from the raw material, in order to make the process as great a commercial success as possible. Dr. Ormandy had spoken of the superiority of the process of the opponents as compared with the German on the question of yield; but, obviously, that gave no indication as to the fineness of the product. The final point was with regard to the use of formaldehyde as an analytical reagent. It was open to the opponents, said Mr. Swan, to call upon the whole of the analytical chemists in London, but they had not called one solitary analytical chemist to say that formaldehyde was an analytical reagent. Mr. Parry, in his vast experience, had never used it, and, therefore, the evidence that it was not an analytical reagent was overwhelming.

Conclusion of the Hearing.

This concluded the hearing, and the referee's decision will be announced in due course.

CHEMISTRY IN THE IRISH FREE STATE.

PROPOSAL TO FORM SEPARATE INSTITUTE.

A SPECIAL general meeting of the Irish Section of the Institute of Chemistry was held at Trinity College, Dublin, on June 1, to discuss the future status of the profession of chemistry in the Irish Free State, Professor W. E. Adeney in the chair.

According to the account of the proceedings in the *Journal* of the Institute, the Hon. Secretary (Dr. A. G. G. Leonard) said it had been suggested to inaugurate a new Institute for Ireland, controlled by a chemical council. Regulations for admission to membership of the new institute had been drafted. President Cosgrave had received a deputation, which had presented a scheme for the organisation, control, and registration of professional chemists in Ireland, suggesting that responsible chemists in the public service and all chemists who desired to give evidence in Courts of Law should be registered by the proposed Irish Chemical Council. The President had received the deputation sympathetically, requesting them to meet him again at a later date, when other members of the Cabinet could be present.

The chief advantages of the new Institute would be—The inclusion of all Irish chemists; the exclusion—with Government authority—of unqualified persons from public appointments; ease of access to the Government, which was sympathetic towards the formation of the organisation; and the provision of an advisory body in connection with Government scientific services.

The following resolution, proposed by Mr. Fagan, and seconded by Prof. Caldwell, was carried unanimously:—

The British Institute to Continue to Function.

"This meeting of the Local Section of the Institute of Chemistry of Great Britain and Ireland approves of the formation of an Irish Institute of Chemistry on the plan put forward in the circular issued by the Committee of Irish Chemists, and it also considers that the Local Section of the Institute of Chemistry of Great Britain and Ireland should continue to function."

Mr. Marlow, the Assistant Secretary of the Institute, said the regulations which had been drawn up seemed, on paper, to be very comparable with those of the Institute of Chemistry of Great Britain and Ireland. In some respects they appeared to be more exacting: he had noted the proposed compulsorily registration of students, and thought that this course was desirable in order that they might build up, during student days, a proper professional *esprit de corps*. In only one respect were the proposed regulations definitely of a lower standard than those of the Institute, and that was in the qualifications proposed for public analysts. It would be possible for an Irish chemist to get the necessary qualification one year after becoming a member of the Irish Institute. The only reference to the Institute in the documents relating to the proposed Irish Institute was the proposal that one representative of the Irish Free State Section should serve on the Chemical Council. He felt that this was an unduly small representation of a body which contained the great majority of qualified chemists in Ireland. He feared that they had been forced to attempt to set up national frontiers in chemistry. He noticed, however, that in their regulations they were including Queen's University, Belfast, and he presumed, therefore, that they had some hope that the present situation between the two parts of Ireland would not affect the practice of chemistry. He trusted, therefore, that they would maintain their standard of qualifications at the high level at which it stood on paper, so that when the present political difficulties had been overcome, and when, as he hoped, Ireland and the other constituent States of the British Empire were completely in amity, it would be possible to say that the Irish Institute was merely a temporary expedient to overcome those difficulties, and that by reason of the maintenance of their standards of qualifications, the two bodies might be fused again into one whole.

THE MONTH IN ENGINEERING.

(Specially Contributed.)

Steam Generation at 3,000lb. Pressure.—The news published this last week or so in the American and British engineering press that a tube boiler is now being constructed at Rugby (Great Britain) to work at over 3,000lb. pressure, is of great interest to chemical engineers, if only because it represents the first attempt actually to work at the critical point of steam and water. As is well known, the latent heat of steam diminishes as the pressure rises. Thus at ordinary atmospheric pressure (14.7lb.) the latent heat of 1lb. of water is 970 B.Th.U., at 50lb. 938.6, at 100lb. 886.7, at 150lb. 869.9, and at 200lb. 848.7. When, however, we begin to approach very high pressures the latent heat falls rapidly, being, for example, 644 B.Th.U. at 1,058lb., and 470 at 2,015lb. If now we continue to heat the water, irrespective of the pressure necessary to prevent it being converted into steam, when the temperature of the water reaches 706° F. and the volume is about three times that at 60° F. (the corresponding pressure necessary being 3,200lb.), the whole mass of the water is suddenly converted into steam at the same volume. That is to say, 706° F. and 3,200lb. pressure is the critical point of steam and water. The exact figures are not yet known, but the above are approximately correct. At this critical point, of course, the latent heat as a factor in the conversion of water to steam will entirely disappear. It must be confessed that the usual explanations of the liquid and the gaseous states are not very lucid, and this question of working at 3,200lb. pressure would seem to be rather a knotty one from the theoretical point of view. The general idea is that a liquid such as water consists of molecules sufficiently close together to exert an influence one upon another great enough to retain the liquid condition, whereas if the molecules are pushed sufficiently far apart they lose this cohesive action and form a huge volume of gas, that is steam.

This extraordinarily fascinating work is being undertaken by Messrs. The Benson Engineering Company, of London, at the Rugby Works of Messrs. The English Electric Company Limited, Messrs. Benson being responsible for the boiler, and Messrs. The English Electric Company for the turbine, which is to work at 1,500lb. steam pressure and 25,000revs. per minute, the combined installation being 1,000kw. The boiler consists essentially of a series of steel tubes, into which the water is forced by hydraulic pumps, and which is heated by means of an oil blast, using superheated air for the combustion. In this way, judging from the laboratory experiments, when the water has traversed approximately 90 per cent. of the length of the coils, it will have been converted at the critical point, and without any absorption of latent heat, into steam. It will then be reduced to 1,500lb. pressure and passed through a second series of coils which act as a superheater and raise the temperature of the steam to about 780° F. It will then be passed into the turbine at this pressure and exhausted again from the turbine at 200lb. pressure before finally passing into the ordinary condensing turbine. It is, of course, only possible to work at pressures like 1,500lb. and over with a boiler in the form of a tube, and the advantage of the Benson method of working at the critical point, and then reducing the pressure, is that the whole of the water can be converted into steam without difficulty, whereas in the ordinary way the formation of steam is violent and spasmodic in the tube, so that such heavy priming results that the method is ordinarily impossible from the practical point of view.

Another Lead-bath Low-temperature-carbonisation Process.—A short time ago there was given in the columns of this paper a description of a lead-bath process for the low-temperature carbonisation of coal, the invention of Mr. J. S. Morgan. Particulars have now just been published of another process in the United States, also using a lead-bath, which has been devised by Messrs. V. Z. Caracristi and Emil Piron. The object of using a lead-bath is to improve the conduction of the heat from the heating medium to the coal, which itself is an extremely bad conductor. In connection with the Caracristi process we understand that a plant has been constructed at Huntingdon, W. Va., U.S.A., which is really a large-scale experimental unit, having a daily capacity of 25 tons, the research work on this plant and in the laboratory extending over the past two years. The firm of Messrs. Henry Ford are strongly interested in the process, and they intend eventually to build a very large low-temperature-carbonisation plant at their River Rouge establishment, Detroit, which will carbonise 4,000 tons of raw coal per day. The intention is to burn the residual low-temperature fuel in the pulverised condition under huge water-tube boilers, which are at present being worked with pulverised raw coal, in conjunction with blast-furnace gas.

The Caracristi process for large-scale working consists essentially of horizontally firebrick retorts, 44ft.—52ft. long, having two horizontal arch chambers 14ft. wide and 6ft 5in. in height, provided with curtain walls at each side to separate the heating and exhaust chambers from the carbonising space. These heating and exhaust chambers are connected by cast-iron **U**-shaped flues in twin form, the lower section of the flues being provided with a bath of molten lead, and having combustion chambers for gaseous firing under the lead-baths, so as to keep the metal in a molten condition. Each of these chambers has a conveyor system made up of three strands of cast-iron plates 3ft. wide and 18in. pitch, held together by steel hinge-pins, being 1in. thick, with flanged ends, with the hinge joints overlapping, so that no cracks can be forced, these flat conveyors riding on the surface of the molten lead. The raw coal is roughly pulverised, and travels through the heating chamber as a thin layer ½in. thick on the lower plates, the actual temperature of carbonisation being just over 1,000° F., the lead being 1,200° F., whilst an elaborate installation of by-product recovery plant and regenerators will also be included.

It is stated that this carbonisation temperature of 1,000—1,200° F. is the most suitable for the plant from the point of view of efficient heat transfer. The remarkable claim is made that carbonisation can actually be completed in five minutes only, so that the plant is of very high productive capacity, the failure in regard to which hitherto has been one of the chief drawbacks of any process of low-temperature carbonisation. The fact that the firm of Henry Ford is associated with the enterprise is sufficient guarantee of its possibilities, although one would think that to keep very large baths or troughs of lead in a molten condition at 1,200° F., presumably for weeks on end, would give much trouble with molten slag on the surface of the lead due to oxidation, and perhaps, also, to organic lead compounds.

The Deterioration of Blast-furnace Linings.—A very important paper has just been read before the American Iron and Steel Institute by Messrs. C. E. Nesbitt and M. L. Bell on "The Disintegration of Firebrick Linings in Iron Blast Furnaces," giving the results of a detailed investigation that the authors have made on this baffling problem. In general the authors are of the opinion that whilst there can be stated to be no very definite position in the blast furnace where deterioration is the greatest, it would appear to be, perhaps, the most marked about 40ft. or 50ft. from the top of the furnace, whilst they also consider that the deterioration of firebrick linings to-day is more severe than it was 15 to 20 years ago. The opinion is expressed that the chief factor in the disintegration of firebricks is the deposition of free carbon within the material of the bricks, and this would seem to be due to the fact that when the bricks contain free or loosely-combined ferric oxides, comparatively large quantities of carbon are deposited, when carbon monoxide is passed over them at a certain range of temperature. The finely-divided carbon deposited in this way exerts a powerful disruptive action and fractures the material readily. The authors have proved experimentally that if carbon monoxide is passed over ferric oxide heated in a glass test tube, free carbon is deposited commencing at a temperature of about 570° F. (300° C.), and the rate increases up to 930° F. (500° C.), when it diminishes, and the action seems to cease at about 975° F. (525° C.). It is possible in the course of 10 hours to have deposited on the top of the ferric oxide no less than 70 times its volume of free carbon, and in this remarkable reaction the ferric oxide appears to be reduced either to a lower oxide or a spongy metallic iron. One or other of these reduced compounds acts as a catalytic agent, breaking up the carbon monoxide bodily into carbon dioxide and carbon, so that the carbon monoxide does not appear to act chemically in the ordinary way.

This would seem to foreshadow some important alterations in the manufacture of firebricks for special purposes, such as the lining of furnaces. The authors recommend that the bricks must be entirely free from uncombined iron oxide, and such bricks can only be manufactured from clay which is similarly free, a condition which can only be realised by weathering the clay in comparatively thin layers of not more than 2ft. thick for several months, so that the iron compounds in the clay will be completely oxidised and give a brown or yellow colour. The portions of the clay which are not coloured must then be converted into bricks.

The Trade Position.—The general position during the month has become decidedly worse, mainly owing to buyers now definitely holding off as far as they possibly can with the object of bringing down the price of both iron and steel. As a result, there has been a very slight drop in prices, but this is regarded by the buyers as nothing like sufficient. The position is becoming decidedly serious. The coke position is somewhat easier, but it is stated that any further substantial reduction in price is impossible with existing working expenses, and there is even talk of shutting down a number of blast furnaces, as stocks are beginning to increase. In almost every engineering centre the same story of a gradual slackening up and disinclination to book orders for the future is told, whilst even the shipments of textile machinery to India and the Far East have diminished. Shipbuilding is particularly badly placed. The sections of engineering dealing with locomotives and colliery material are quite busy, whilst the electrical industries are also fairly good. The colliery industry, also, is beginning to share the general depression. At present the position is quite satisfactory in that the output of the mines is being sold, and congestion at the docks is being relieved by the method of working in three shifts. The position as regards future orders, however, is not quite so cheerful, and there is a tendency in France, Italy, Holland, and Scandinavia to avoid buying as much as possible, in the hope of reducing prices. In May the export figure reached 7,684,405 tons, which is a record for Great Britain, but it seems to be the general opinion that the boom due to the Ruhr difficulties is definitely coming to an end.

NOTES ON THE ITALIAN CHEMICAL INDUSTRY.

(From Our Own Correspondent.)

National Congress of Chemistry.—The first national congress of pure and applied chemistry was held in Rome from June 3 to June 7. Amongst the subjects discussed were the questioins of the national fuel, the necessity of rendering compulsory the debenzolisation of coal gas, the bituminous schists of Ragusa, a new method for the valuation of fertiliser materials, phosphoro-manganese as a fertiliser, and the production of potash from leucite.

Italian Asphaltic Minerals.—Considerable attention is now being paid to the question of the utilisation of the asphaltic rocks of Italy. These rocks, which contain large amounts of bitumen, occur in the province of Syracuse, where workable deposits estimated at 320,000,000 tons exist. Plant now working and in course of erection will ensure an annual production of 50,000 tons of crude oil from the distillation of 1,000,000 tons of shale. The oil, which is obtained by a simple method of distillation, is used directly as a fuel for Diesel engines and as an illuminant for flare lamps.

Revision of the Customs Tariff.—There is every probability that considerable alterations will be made in the Italian import tariff in the near future. A commission representing Italian industrial and agricultural interests has been negotiating at length with a Governmental Sub-Committee, and agreement has been reached on most of the points in dispute. About 600 clauses will be deleted from the import tariff, although the objection has been raised that this would diminish the value of Italo-French and Italo-Swiss commercial treaties, and also the "most favoured nation" clauses. So far as chemicals are concerned the import duty on copper and copper compounds will probably be abolished entirely. It is proposed to reduce the import duty coefficients of crude glycerine from 8 to 5, and on refined glycerine from 10 to 8. The co-efficient on nitrobenzol, aniline, crude toluidine, aniline hydrochloride, and other aniline salts is to be increased from 0.5 to 1.0. The Italian Government will reserve to itself wide discretionary powers in modifying the tariff from time to time, but the general effect will be to ease matters decidedly for importers into Italy.

Company News.—At a recent meeting of the Società Italiana della Celluloide, of Castiglione Olona, the increase of the capital from five to ten million lire was discussed. The Società Italiana del Fosforo, of Milan, is to increase its capital from 300,000 to 1,800,000 lire. The Società Anonima Chimica Lombarda A. E. Bianchi e C., of Rio, near Milan, is considering the reduction of its capital from 12,000,000 to 9,600,000 lire. At Lodi the firm of Anonima Lavorazione Catrame e Sottoprodotti e Prodotti Chimici was founded with a capital of 350,000 lire. The Società Anonima Italiana Silicati was formed at Naples with a capital of 60,000 lire, for the manufacture of the silicates of soda and potash from the siliceous sands in possession of this firm, by means of a patented process of Dr. Reggianini. At a meeting of the mercury firm "Monte Amiata" Società Anonima Mineraria, that has its headquarters in Abbadia S. Salvatore, it was announced that during the past financial year a net profit of 1,531,510 lire was made, and a dividend of 5 lire per share of 50 lire will be paid. At Taranto the Società Tarantina Ossigeno Ing. Graramo e C., with a capital of 440,000 lire, was formed for the production, application, and utilisation of oxygen. The Società Anonima Consorzio Romagnolo per l'Industria Tartarica, of Ravenna, closed its balance at the end of 1922 with a loss of 394,650 lire. The year's working of the Società Italiana del Radium, of Rome, in 1922, showed a net profit of 35,974 lire on a capital of 600,000 lire, enabling a dividend of 5 per cent. to be paid. With a capital of 500,000 lire there was established at Milan the firm of Fabbrica Prodotti Chimici Dott. Oscar Tobler, for producing special chemicals. At Milan the firm Società per l'Esercizio Impianti Chimici, with a capital of 300,000 lire, was founded for the manufacture of chemical plants. At Milan the Società Italiana Commercio Internazionale Solfati, with a capital of 4,000,000 lire, has been formed for trade in chemicals and non-ferrous minerals.

Italian Overseas Chemical Trade.—During the first quarter of this year Italy imported inorganic chemicals to the value of 25,813,362 lire, fertilisers valued at 36,887,066 lire, organic chemicals at 8,974,703 lire, and mineral oils, resins and gums at 156,409,669 lire; exporting inorganic chemicals to the value of 12,473,914 lire, fertilisers valued at 723,268 lire, organic chemicals at 26,873,577 lire, and mineral oils, resins and gums at 1,428,572 lire. During 1922 Italy imported 555,536 tons of mineral phosphates, against 567,543 tons in 1921; 56,371 kilos of essential oils and essences, against 83,489 kilos in 1921; 5,814 tons of acids, against 9,160 tons in 1921; 3,750 tons of oxides, against 1,906 tons in 1921; 106,067 tons of fertilisers, against 68,025 tons in 1921; and 27,999 tons of fats, against 16,422 tons in 1921. Other imports during 1922 were as follows: Ammonia 1,703 tons, caustic potash 683 tons, nitric acid 1,458 tons, bicarbonate of soda 2,074 tons, chloride of ammonia 609 tons, bleaching powder 846 tons, calcium chloride 955 tons, nitrate of potash 1,369 tons, aluminium sulphate 1,796 tons, sulphate of barium 946 tons, sulphate of copper 3,949 tons, sulphate of soda 12,328 tons, sulphate of soda and potassium 2,218 tons, silicate of soda 5,017 tons, refined glycerine 248 tons, and pyrolignite of lime 2,018 tons.

General Notes.—Professor Fachini has presented to the Oils and Fats Bureau, at Milan, a valuable memorandum on the present state of the soap and glycerine industries. Included in this report is a new method for the analysis of glycerine, which is claimed to be both rapid and accurate. The professor has continued his work on the elaboration of methods for the differentiation between glycerine of animal and vegetable origin, a point shown to be of distinct importance during the war as affecting the stability of nitro-glycerine explosives.

The Italian Ministry for War has established a chemical military service to investigate experimentally and practically the physiological effects of the various chemical warfare materials. So far as known at present, no centralised body has been formed, but the decree authorising the formation of the branch has been submitted to all the chemical manufacturing firms in Italy.

The Fauser process for the synthesis of ammonia as worked at the Società Elettrochimica Novarese at Novara (see *Chemical Trade Journal and Chemical Engineer*, May 25, page 631) is proving very successful, and negotiations are being carried on with a view to exploiting the process at other plants. The Società Italiana Prodotti Azotati has already sold this year 289,598 quintals of nitrogenous fertilisers. In 1922 Italy consumed 334,220 quintals of cyanide, as against 160,000 quintals in 1921. The maximum pre-war annual consumption was only 280,000 quintals. Sales of sulphur during June were the largest this year, important contracts having been signed at Paris by the representatives of the Consorzio Zolfifero and important English firms.

INDIAN OILSEEDS CROP.

INCREASED YIELDS ANTICIPATED.

According to the forecast issued by the Department of Commercial Intelligence in India, the estimated figures are based upon reports received from provinces which contain 98.7 per cent. of the total area under rape and mustard, and 99.2 per cent. of the total linseed area in British India. Of the Indian States, estimates are furnished by Hyderabad, Baroda, the States in the Bombay Presidency, six Feudatory States in the Central Provinces, and the States of Alwar and Kotah in Rajputana. The condition of the crops is reported to be generally good, except in Bengal, where the plants were adversely affected through continued absence of rain.

The total area under rape and mustard amounts to 6,213,000 acres, which is 2 per cent. below the finally revised area of last year. The total estimated yield is 1,213,000 tons, as against 1,167,000 tons, the revised final figure of last year, or an increase of 4 per cent. In addition to the areas for which particulars are given above, rape and mustard are grown in certain other tracts in British India, and the average area so grown for the last five years has been some 79,000 acres, with an estimated yield of 15,000 tons.

The total area under linseed is returned at 3,358,000 acres, which is 11 per cent. above the area of last year. The total estimated yield is 532,000 tons, as against 436,000 tons last year, or an increase of 22 per cent. In addition to the areas for which particulars are given above, linseed is grown in certain other tracts in British India, and the average area so grown for the last five years amounts to about 24,000 acres, with an estimated yield of 4,000 tons.

BRUNNER, MOND & COMPANY.

JUBILEE CELEBRATION DINNER.

MR. ROSCOE BRUNNER presided at a dinner at the King Edward VII. rooms, Hotel Victoria, London, on Friday last, attended by over 200 guests, and given by the chairman and directors of Brunner, Mond and Co., Ltd., to celebrate the fiftieth anniversary of the founding of the Winnington Works.

Brigadier-General Sir William Alexander, proposing the toast of "Brunner, Mond and Co., Limited," said that looking back on the history of fifty years, whose culmination they were celebrating, they recognised a great record of splendid achievement and worldwide usefulness. They were celebrating the jubilee of the most successful industry of its kind. What were the landmarks in that pilgrimage of success? The success of Brunner Mond's had been the result of the marriage of brains with hard work. It was in 1873 that Ludwig Mond and John Brunner built the first plant at Winnington, faced considerable difficulties at first with courage, and finally solved them. The most eloquent tribute was the existence of the most important ammonia soda works in the world. The founders had had worthy successors. Mr. Roscoe Brunner, the bearer of a famous name, was a live wire, and was upholding the traditions of courage and service. Was it any wonder that the output of the works in 1881 was multiplied by twenty-eight times in 1922?

Mr. Roscoe Brunner, in reply, said that regrets at inability to attend had been received from the President of the Board of Trade, the Minister of Labour, and Mr. J. M. Beck (the United States Solictor-General). They were proud of their founders and their success, but prouder of the founders' principles and prouder still, perhaps, of this—there have never been Brunner men and Mond men. All who have worked for the firm have been Brunner-Mond men, and continued to be so. Nearly 20 per cent. of their present workers had been with them for over twenty-five years. He claimed that as an illustration of their team work.

Brunner-Mond's had always been a great family, and that was one of the key reasons of its success. That spirit had been maintained, and all who had been engaged in industry know how difficult it had become to maintain that relationship compared with the days when most of the men were known by their Christian names. They had endeavoured by the works council to keep in touch and harmony with those who represented the men. They were not resting on their oars. Looking back to the past only stimulated them to greater endeavours.

The Endowment of Science and Research.

Sir John Brunner, who proposed "Science," recalled hearing his father say, "I owe everything to the application of science to industry." He thought the chemical industry should try to repay the debt it owed to science. It ought to foster research. The Government did very little, and for the time they had lost the help of the German scientific men. It was hard enough for them to live in Germany now without publishing their results. His company hoped to endow and foster research in this country.

Sir J. J. Thomson, whose name was coupled with the toast, replied. The toast of "The Guests" was submitted by Mr. G. W. Balfour, and responded to by Mr. Walter Leaf and the Vice-Chancellor of the University of Cambridge. "The Chairman" was proposed by Sir Max Muspratt.

THE POSITION OF THE PUBLIC ANALYST.

REMUNERATION AND STATUS UNSATISFACTORY.

THE Council of the Institute of Chemistry and the Council of the Society of Public Analysts view with grave concern the attitude of the authorities towards the remuneration, conditions of service, and fixity of tenure of public analysts and official agricultural analysts. The Public Appointments Committee of the Institute have therefore prepared a statement on the conditions of appointment of public analysts, which is being printed and circulated among the public authorities concerned with the administration of the Sale of Food and Drugs Act. This statement, which is also reprinted in the June issue of the *Journal and Proceedings of the Institute*, is rather lengthy, but the whole position as stated by the Institute is summarised as follows:—

The duties of the public analyst are daily increasing in complexity and in difficulty. Higher qualifications than formerly are required of him, not only owing to the general advance in science as applied to the analysis of food and drugs, but also by the exacting character of the numerous regulations of the Government Departments concerned. In 1919, following upon insistent representations to public authorities administering the Acts, the remuneration of public analysts, which had hitherto been totally inadequate, was, in the majority of cases, improved. Unfortunately, however, even this improved remuneration was insufficient having regard to the greatly increased working costs.

The position is becoming still more unsatisfactory owing to a tendency on the part of local authorities, especially in the cases of new appointments, to revert to the pre-war scale of remuneration. Further, the tenure of office of public analysts is insecure; the relative official position of the public analyst to other officers is sometimes not clearly defined or understood by local authorities, and, except in isolated cases, no provision is made for the inclusion of public analysts in any superannuation scheme. The Council of the Institute of Chemistry and the Council of the Society of Public Analysts are of opinion that, unless the conditions attached to the appointments of public analysts are improved, they will cease to attract professional chemists of the proper type.

Scale of Remuneration Recommended.

They recommended that, in the case of public analysts other than those whose laboratories and staffs are provided by the authorities, whatever be the exact method of payment—by fee per sample or by a combination of salary and fee—the remuneration should be at the rate of not less than £1 1s. per sample for the first 100 examined, and not less than 15s. for each sample beyond that number.

BRITISH CHEMICAL AND DYESTUFFS TRADERS' ASSOCIATION.

IN the bulletin dated June 30 it is stated that at the last meeting of the Executive Committee a further seven firms were elected members.

Reparations Dyestuffs.

In the past all reparation dyestuffs, upon importation, have been reserved for consumers for 14 days. This will be shortly modified, and the period allowed consumers will be reduced to 7 days from the time of arrival of each consignment. The discounts to purchasers of large quantities will continue as hitherto. The importation of dyestuffs from Germany as reparation will cease in December, 1924. America has ceased to take delivery of colours from Germany as reparation, and the quantity allowed this country has consequently increased.

The Safeguarding of Industries Act.

Several members of the B.C.D.T.A. complained recently that Customs have detained and sampled imports of chemicals that are in no way connected with the Safeguarding of Industries Act, and have held them pending result of analysis. This has often meant five or six days delay. In many of these instances the goods have been in barges and importers have thus suffered financially through Customs action. This question is being taken up with the authorities. In almost every case the B.C.D.T.A. can secure the immediate release of the goods, and thus save members from incurring charges in respect of demurrage on barges, etc.

Trade with Occupied Germany.

Some few weeks ago notices were issued advising British importers they could obtain delivery of all goods from the Occupied Territories ordered before February 20 last. The German exporter had to get a licence from, and pay a duty to, *his* Government, and the British importer had to get a licence from, and pay a tax to, the Franco-Belgian authorities. When these regulations were complied with, it was understood that there would be no difficulty in getting such goods through. Unfortunately, in the numerous instances in which members have applied for Franco-Belgian licences and signified their willingness to pay tax, it has been found that in practice the facilities mentioned above were not worth the paper they were printed on. Some firms have gone to the length of sending representatives over to endeavour to obtain release of their goods, but after some weeks, they have met with very little success. They express the opinion that until a settlement of the reparations question is made there is little or no hope of carrying on business, either export or import, with Germany (Occupied Territories).

LEGAL INTELLIGENCE.

MANUFACTURING CHEMISTS' FAILURE.

Preston, Hull and Co., Ltd.

Under a winding-up order dated January 16 last, the statutory meetings of the creditors and of the shareholders were held on June 29. The Official Receiver, who presided, said the company was registered on January 14, 1920, with a nominal capital of £12,500., and was promoted by Colvin Percy Preston to acquire as a going concern the business of manufacturing druggists and chemists which he and his wife had carried on at 112, High Holborn. Mr. Preston was appointed managing director at a remuneration of £350. per annum, in addition to which he received an allowance in respect of expenses and 7½ per cent. of the net profits of the company. Towards the end of the year the company opened branches in Manchester, Newcastle, and Birmingham, but these did not appear to have been a success and about the middle of 1922 they were closed. The trading account for the year ending December 31, 1920, disclosed a gross profit of £7,753., but a net loss of £764., the sales for the year amounting to £11,768. The profit and loss account included £1,978. for advertising. During the ensuing twelve months the gross profits fell to £3,897., while there was net loss on the trading of £7,795., the profit and loss account including salaries, £4,460. No further accounts were prepared. The statement of the company's affairs filed in the liquidation disclosed £7,444. due to 64 unsecured creditors, as against which the assets were valued at £378., which mostly consisted of book debts.

As a result of the meetings the liquidation remained in the hands of the Official Receiver.

FAILURE THROUGH LABOUR TROUBLES.

Insulators, Ltd.

On Wednesday, July 4, the statutory meetings of creditors and contributories were held in the liquidation *re* Insulators, Ltd., Bidder Street, Canning Town. Mr. E. T. A. Phillips, Official Receiver, presided. The statement of affairs showed unsecured liabilities £21,523. and assets £877., and the total deficiency as regards contributories amounted to £102,186. The Chairman said the company was promoted in September, 1919, with a nominal capital of £75,000., subsequently increased to £150,000., to carry on business as manufacturers of and dealers in insulating materials for cold storage, and to deal in and instal apparatus for cold storage premises and chambers. The promoter, in the course of his research work discovered a new chemical composition which he named "Insulite" and which he claimed to be wear, fire, water, and vermin proof, and to be suitable for use as a covering for the decks of ships, and as a floor covering where protection from heavy traffic was required. The company acquired the secret process, the freehold factory at Canning Town, stock, plant, and trade named for £53,500., which was paid as to £15,000. in cash and the balance in shares. Owing to labour troubles and depression in shipbuilding, the trading was carried on at a loss. The liquidation remains in the hands of the Official Receiver.

BREACH OF A SOAP CONTRACT.

J. Strother and Co. *v.* H. T. Manning and Co.

In the Mayor's and City of London Court, on Friday, June 29, before Judge Shewell Cooper, Mr. Joseph Strother, trading as J. Strother and Co., Peninsular House, claimed £29. 6s. 10d. against Messrs. H. T. Manning and Co., import and export merchants, 133, Fenchurch Street, E.C., damages for breach of contract to deliver 100 gross of small toilet soap at 5s. per gross as sample. Plaintiff said the soap was wet and dirty, very old and of poor quality and not properly packed, and in many instances crumbled and commercially valueless. Defendants took up the view that they could not accept any responsibility for the soap after it left the warehouse, and that the damage must have been done in transit. The transit was only to Woking, and being summer weather in May it could not have got damaged in four days between the despatch and the complaint.

The defendant, Mr. Manning, said he purchased a thousand gross of the soap in question in November last, and it came from the Continent, he believed, where it was manufactured. He bought it from a London merchant. The soap was not in the condition presented by the samples now shown to the Court, when it was sent out from his warehouse. It was then approximately clean, and in about the same condition as the sample boxes which were shown to the plaintiff at the time of the sale. Apparently the soap had received some extraordinary treatment after it had left his warehouse.

Judgment was given for the plaintiff for the amount claimed with costs.

ACTION AGAINST A CHEMICAL COMPANY.

Turner Drug and Galenical Co., Ltd.

In the Chancery Division on Tuesday, Mr. Justice Russell was asked to make a declaration for judgment in default of defence in the debenture holders action of Fogden v. Turner Drug and Galenical Co., Ltd., of Ilford. Plaintiffs claimed to be entitled to a charge on the company's property, and asked for an account of what was due under debentures.

Counsel for plaintiff said the company was incorporated in 1920 with the object of carrying on business as manufacturing and analytical chemists. Plaintiffs were not only debenture holders, but also mortgagees of the freehold. The company had ceased to carry on business, and payment of the debentures therefore became due.

The company was not represented, and his Lordship made the declaration asked for.

THE STANDARDISATION OF DISINFECTANTS.

PROPOSALS OF THE PHARMACEUTICAL SOCIETY.

An important matter to all users of disinfectants in large quantities was raised at a Council Meeting of the Pharmaceutical Society of Great Britain on Wednesday, July 4. Mr. E. T. Neathercoat (president) was in the chair.

Sir William S. Glyn-Jones, secretary and registrar of the society, reported that a sub-committee had considered at considerable length the subject of the fixation of standards of strength for lysol and chlorodyne. At present there was no standard whatever, and users were much troubled by the considerable variation of strength existent in the various fluids on the market. The Law Committee of the Society had also reported on the matter and agreed with the previous committee that the Ministry of Health should be approached as to the desirability of fixing standards of strength in regard to both lysol and chlorodyne.

Mr. Melhuish pointed out that there were two kinds of lysol on the market, and both differed very considerably in cresol content, and some law was very necessary on the subject. Mr. White took the view that lysol had many characteristics different from all other disinfectants, and that accordingly it would probably be more in their interest to press the Ministry of Health to create standards in this matter.

The President said the points raised had been very valuable ones, but in the meantime he proposed that the original recommendations of the two committees should be adhered to, and that action in regard to disinfectants in general should be deferred for the time being. This course was agreed to.

OUR BOOKSHELF.

Alcoholic Fermentation. Arthur Harden, Ph.D., D.Sc., F.R.S. London: Longmans, Green and Co.; 6s. 6d. net.

Considerable re-arrangement of subject matter and extension of bibliography is noticeable in the 3rd edition. The function of phosphates in fermentation—chemical changes in fermentation—inhibiting and accelerating agents—by-products, etc., form chapters of scientific and practical interest, the importance of which needs no emphasising.

Practical Bacteriology for Chemical Students. David Ellis. London: Longmans, Green and Co.; 4s. 6d. net.

There are many chemists in industry whose training has not called for or included bacteriological study, but who nevertheless would like to obtain a grasp of its general principles. It is a branch of science the application of which will continue to crop up more and more in all sorts of unlikely quarters, and we can do no better service to industrial chemists generally than to call their attention to a very practical little volume at a moderate price.

ITEMS OF INTEREST.

British Coal Output.—The output of coal for the week ended June 23 was 5,588,200 tons, compared with 5,651,100 tons in the preceding week, and 4,353,900 tons a year ago.

Smuggled Saccharine.—At Hull, Mirosslar Skrivanik, a Czech, was fined £1,609, being the single value and duty on 218lb. of saccharine which he was charged with concealing.

Institution of Gas Engineers.—The Institution of Gas Engineers, recently holding its annual conference at Belfast, announces the following elections to office for the ensuing year:—President, Mr. Samuel Tagg; vice-president, Mr. J. Ferguson-Bell; hon. secretary, Mr. W. E. Price.

Barrow Furnace Damped Down.—Owing to the falling-off in the demand for iron the Barrow Steel Company have put out of blast a furnace on the ironworks side of the establishment, leaving only two blowing. The output has been decreased at other works, and there is also less activity in the iron mines. Barrow steel mills remain employed.

Institute of Chemistry.—The Council propose to hold conferences from time to time in centres where sections of the Institute have been formed. The first conference will be held at Liverpool in October. The proceedings will occupy at least two days, and will include an open debate upon the affairs of the profession and of the Institute generally.

British Association.—Arrangements have been made to broadcast the presidential address of Sir Ernest Rutherford to the British Association in Liverpool on September 12. In addition to the sectional meetings, it is proposed to hold a series of citizens' lectures in Liverpool, Birkenhead, Warrington, Wigan, and Southport. It is anticipated that 3,000 to 5,000 people will visit Liverpool for the meeting.

Business Notices.—We understand that Dr. G. N. White has joined Messrs. Oscar Guttmann and Sons, consulting engineers and chemical advisors, of 7 and 8, Idol Lane, Eastcheap, London, E.C.—We are informed by Messrs. Thomas Broadbent and Sons, Ltd., of Central Ironworks, Huddersfield, that their works will be closed from 5 p.m., July 20, to 9 a.m., July 30, on account of the annual holidays.

Fire.—A serious fire occurred on Thursday of last week in the premises of Messrs. Pinkerton, Gibson and Co., wholesale druggists and manufacturing chemists, North East Thistle Street Lane, Edinburgh. After three hours' work the firemen got the outbreak under control. Considerable quantities of stores were destroyed, and much damage done to the floors and joisting, and also to the roof. The outer walls of the building, however, remain intact.

Institution of the Rubber Industry.—An appeal for funds is being made by the Institution of the Rubber Industry, with the object of placing the Institute upon a firm and permanent foundation. This, it is hoped, may be accomplished by attracting more members, and partly with this object in view, and also because the Executive believes in the desirability of fresh activities, it is proposed to extend the lectures, etc., arranged by the Institute and to found a technical entrance examination.

Home Grown Sugar.—Sir Ernest Jardine, Bart., presiding last week at the third annual meeting of Home-Grown Sugar, Ltd., expressed the hope of the board that the results of the coming season would enable the company to pay a dividend on the reduced capital next year for the first time without calling upon the guarantee of the Government. The directors' report and accounts were adopted, and the guaranteed dividend of 5 per cent. provided by the Government for the past year was declared.

The Separation of Isotopes.—Dr. F. W. Aston, who delivered a lecture on this subject before the annual meeting of the Society of Chemical Industry at Cambridge, said he could assure chemists that any separation of isotopes that could be done in the laboratory by any artificial means was so small that it need not change the chemical constants or equations of chemistry for many years to come. Also, there was no process in nature, apparently, which would separate isotopes, and though an enormous amount of labour had been spent on determining various elements from different sources, no change from the correct chemical atomic weight had been achieved. The only exception was lead, but in that case the lead was made by a radio-active process, and it was not in the same category as the other elements.

German Manufacturers in U.S.—It is reported that three German bankers have arrived in America, intending to manufacture soap and chemical products, using German chemists and processes.

Change of Address.—The Magnesium Co., Ltd., announce that as from June 30 the company's address will be 78, Hatton Garden, London, E.C. 1. Telephone No., Holborn 6830/8, and telegraphic address, "Ognesiuma, Smith, London."

Chilean Iodine Combine.—The Chilean Iodine Combine, which under its former organisation was to have terminated on March 31 last, has extended its time of existence as such to June 30. The proposed reforms in the statutes have now been drawn up and will be submitted to those interested in the industry. Under these new regulations, the old Iodine Combine will become the Association of Iodine Producers of Chile.

Mining Subsidence.—The Royal Commission on Mining Subsidence has decided to take evidence in public. Evidence will be invited, in the first place, from the Government Departments concerned as to the existing law and conditions with regard to matters covered by the inquiry. This evidence will be opened on October 16, and a further announcement regarding that meeting will be made in due course.

Tariff Notes.—As from June 4 last, sulphate of copper imported into Roumania is to be exempt from import commission tax.—The duty on tar imported into San Salvador has been reduced to 3 centavos (gold) per kilog. As from August 7, a duty of 5 per cent. is imposed on exported sugar when the declared value is 4 dollars and more per quintal of ·46kilogs.—The Swedish sugar import monopoly has been withdrawn from June 1. Sugar may now be imported without restriction.

Distinguishing Caffeine from Theobromine.—Caffeine may easily be distinguished from theobromine by means of the Nessler's reagent, states O. Frey (*Pharm. Monatshefte*, 1922, No. 6). The former gives a red colouration after about a minute. If the mixture be left to stand for an hour or so and then boiled for three minutes, a dull-red precipitate is obtained. Under similar treatment theobromine gives a pale-brown colouration. The presence of antipyrine vitiates the reaction.

Cape Explosives Debentures.—The Cape Explosives Works, Limited, 7½ per cent. debenture stock will be redeemed on January 1, 1924. The amount outstanding is about £1,000,00. sterling. The stock, offered at 93, is now quoted at 103, the redemption price fixed by the prospectus. The stock is not due for repayment till January, 1944, but the company is exercising its powers to redeem it on six months' notice. The existing security will be exchanged for new debenture stock, which will undoubtedly carry a lower rate of interest.

The Institute of Metals.—The annual autumn meeting will be held this year in Manchester on September 10—13. The meeting will open with the second annual autumn lecture, to be delivered by Lieut.-Col. Sir Henry Fowler, K.B.E., on "The Use of Non-Ferrous Metals in Engineering." The lecture will be a popular one, and is open to the public, tickets being obtainable from Mr. G. Shaw Scott, M.Sc., 36, Victoria Street, London, S.W. 1. The mornings of September 11 and 12 will be devoted to the reading and discussion of papers. Visits will be paid to several large works in the vicinity of Manchester. With the exception of the autumn lecture, the meetings are open only to members and students of the Institute.

British Laboratory Equipment.—The Council of the Institute of Chemistry have received from the Department of Scientific and Industrial Research a request to nominate three or four members to furnish information with regard to the quality and technical range of British production of optical glass and instruments, laboratory glass and porcelain, synthetic organic chemicals, analytical reagents, and other fine chemicals. The Department had already sought the opinions of a large number of professors of chemistry, physicists, and others, but, comments the *Journal* of the Institute, appeared to have addressed inquiries to very few practitioners in chemistry. The Council have forwarded the names of Mr. W. T. Burgess, Dr. J. T. Dunn, Dr. Bernard Dyer, Mr. E. W. Voelcker (hon. treasurer), together with that of Mr. H. W. Cremer, who is responsible for supplies in the chemical department of King's College, London.

PARLIAMENTARY NEWS.

Fertilisers and Feeding Stuffs Act.

In the House of Commons on Thursday, June 28, Mr. Turton asked the Minister of Agriculture: whether he is aware that county councils are prohibited from instituting proceedings against offenders under the Fertilisers and Feeding Stuffs Act, 1906, unless and until the Ministry has given its consent; and, if so, whether he is prepared to bring in a Bill to remove this restriction?

The Minister of Agriculture (Sir Robert Sanders): The answer to the first part of the question is in the affirmative. I am taking steps to appoint a Departmental Committee to inquire into the working of the Act referred to, and to report as to what Amendments, if any, are desirable.

Pitch Cancer.

Mr. D. Williams asked the President of the Board of Trade the number of men certified as suffering from pitch cancer by those engaged in the manufacture of pitch and patent fuel during the past five years; how many have died of this disease during the same period; and how many employed in those industries have died in the same period from other forms of cancer; and whether, in view of the growth of this disease, he will make it obligatory on the manufacturers of these commodities to use mechanical appliances in the handling of pitch wherever possible?

Mr. Bridgeman: The numbers of men reported to the Factory Department as suffering from this disease during the five years 1918 to 1922 were as follow: In 1918, 23; in 1919, 10; in 1920, 25; in 1921, 18; and in 1922, 15. No fatal cases were reported in 1918 to 1920; two were reported in 1921, and one in 1922. Before 1920 the disease was not compulsorily notifiable under the Factory Act, but cases were notified under a voluntary arrangement. The figures do not indicate any growth in the incidence of this disease. I regret that no information is available to show the number of deaths in these industries during the period in question from other forms of cancer. As regards mechanical appliances, I understand that these are generally used where practicable, but that they can only be used in a few operations. I am advised that the most effective precautions against this disease are great attention to personal cleanliness and periodic medical examination, and that facilities to enable the worker to take these precautions have been arranged for at the instance of the Factory Department at all the works concerned.

German Reparation Duty.

Sir W. Joynson-Hicks, replying to Mr. W. A. Jenkins, said: The amounts collected by the Commissioners of Customs and Excise under the provisions of the German Reparation (Recovery) Act are as follows:

Year ended March 31, 1922	£3,709,000
Year ended, March 31, 1923	£7,474,000
Two months ended May 31, 1923	£1,397,000
Total	£12,580,000

The percentage rate of the levy was reduced from 50 to 26 as from May 13, 1921.

Exports of Coke.

The Secretary for Mines (Lt.-Col. Lane-Fox), replying to Mr. Smedley Crooke, on July 2, said: The following statement gives the average price f.o.b. of export coke and the total amount of coke exported during the first quarters of 1922 and 1923 respectively.

—	Total Amount of Coke Exported.	Total Value.	Average Value Per Ton (f.o.b.).
1st Quarter, 1922.	Tons.	£	s. d.
Gas coke	226,068	345,046	30 6
Other sorts	296,289	451,088	30 5
Total coke	522,357	796,134	30 6
1st Quarter, 1923.			
Gas coke	294,553	428,941	29 2
Other sorts	489,237	863,654	35 4
Total coke	783,790	1,292,595	33 0

SOUTH WALES NOTES.

[Specially Contributed.]

There is not much new business being booked for tinplates. The bulk of trade in this industry is controlled by merchants, and the latter seem to be waiting for a fall in quotations. There is every sign that prices will be easier, inasmuch as the steel makers are now experiencing a dull time and have to stock in order to keep their mills going, while the prices of raw materials used in the make of tinplates are cheapening. On the whole the returns show that the volume of trade is steadily expanding. Patent fuel manufacturers, owing to more abundant suplies of small coal and easier conditions in supplies of "binding" materials, are offering better terms for briquettes and some of the best brands can now be purchased at £1. 17s. 6d. per ton f.o.b. Algeria, France, and Italy are at present the most important buyers, but other countries are sending better inquiries, and home demands are on the increase. In the iron and steel industries considerable anxiety prevails and bookings do not look very good at the moment, many works having only some two or three weeks' orders in hand. Galvanised sheet makers have slightly lowered their prices. The non-ferrous metals trade is somewhat dull, with little prospect of improvement in the copper trade. Cokes are getting plentiful and the furnace qualities show a tendency to ease in price. Foundry cokes are in strong demand. The ovens are working well, by-products being in good call, with the exception of sulphate of ammonia, which is somewhat neglected.

The imports to Swansea for the week were 11 tons copper ore from Lisbon, 3,266 zinc concentrates from Port Pirie, 10 tons ferro phosporus, and 15 tons spelter from Hamburg, 495 tons phosphate of lime from Antwerp, 1,462cwt. nickel oxide from Montreal, 1,315 tons pyrites from Wyborg, 5,040 tons pitch from Pensacola, and 200 tons iron pyrites from Pomaron; imports to Port Talbot, 2,829 tons precipitate of copper from Huelva; to Llanelly 238 tons basic slag from Ghent; to Cardiff 100cwt. nickel from Antwerp, 2cwt. olive oil from Bilbao, 32 tons phosphorus from Montreal, and 40 gallons acetic acid from Rotterdam. The exports from Newport included 4 tons salammoniac and 11 tons zinc chloride to Bombay.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, whence, unless otherwise stated, further information may be obtained.

Belgium.

A Belgian firm at Antwerp desire to secure the agency of British firms manufacturing perfumery, druggists' sundries, etc. (Ref. No. 814.)

Italy.

An agent in Milan desires to secure the representation for Italy of British exporters of shellac, gum arabic, etc. (Ref. No. 818.)

Poland.

An agent in Warsaw desires to secure the representation of British firms in caustic soda, tallow, and ethereal oils. (Ref. No. 823.)

Spain.

A commission agent in Tortosa is desirous of representing British firms for the sale of chemical products and fertilisers. (Ref. No. 824.)

Spain and Portugal.

The Spanish-speaking principal of a British firm of exporters, who is shortly visiting the chief centres in Spain and Portugal, is prepared to act for British manufacturers of chemicals and other lines, with a view to introducing their products into these countries, the appointment of local agents, etc. Terms: commission on results basis. (Ref. No. 826.)

United States of America.

A firm of importers in San Francisco wishes to communicate with British producers of sulphate of ammonia, superphosphate and other fertilisers, with a view to obtaining agencies for the Pacific Coast of the United States. (Ref. No. 833.)

FERTILISER NEWS.

Nitrate of Soda.—Shipments during the latter half of last month were on a much heavier scale, being almost three times the quantity exported in the first fortnight. Total shipments, therefore, amounted to about 165,000, of which 75,000 tons was due for Europe, 55,000 tons to the United States, and 35,000 tons to Japan and other customers. Production being estimated at about 150,000 tons, coast stocks were accordingly reduced to about 983,000 tons. With the stocks in consuming countries, together with material afloat, reaching the figure of 272,000 tons, the visible supply as at June 30 last, therefore, amounted to 1,255,000 tons, statistically much better than in previous years, and, in fact, below the figure for June 30, 1914, by some 10,000 tons. Sales by the Producers' Association have been well maintained, and so far amount to about 880,000 tons for the coming season. There is reported to be some change in the tendency of the market, however, and the quantity destined for European ports (including Egypt) is larger than the amounts for the United States and other countries combined. The demand from America, in fact, is falling off, although it is early yet to anticipate the further sales. Deliveries from ports in Europe and Egypt at 75,000 tons during June exceeded imports by 37,000 tons, and stocks were correspondingly reduced by that amount. There were, however, reshipments from Antwerp and Holland to various other European and Egyptian ports involving a total of 6,500 tons. The improved weather on the Continent has doubtless been responsible for the increased consumption, though it should be remembered that consumption is by no means synonymous with "port deliveries." Large orders having been booked on the new season's account, reports are already reaching this country from Chile pointing out the difficulties confronting producers, entailing heavier production costs. If the scale of production is to be increased, as is anticipated, the scarcity of labour is likely to prove a serious obstacle. This, of course, may be the peg on which to hang a higher price list, but increasing production of other and cheaper forms of nitrogen may cause the Chilean producers to reflect on the probable result of such a manœuvre.

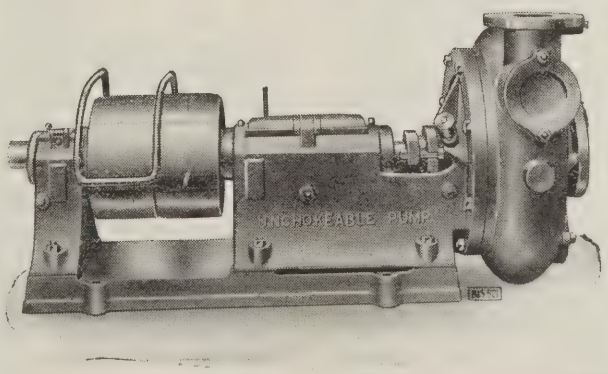
Sulphate of Ammonia.—The situation in the fertiliser market being very different to that obtaining twelve months ago, it was to be anticipated that the price of sulphate of ammonia would be reduced for the ensuing season. The extent of the reduction, as revealed in the circular just issued by the Federation, is considerable, and should stimulate the consumption of the fertiliser in the United Kingdom. For July and August delivery, sulphate of ammonia is on offer for home agricultural use at £14. 15s. per ton for neutral quality in fine friable condition, free from lumps, having a basis of 25¾ per cent. ammonia. This price is for lots of 4 tons and upwards, delivery to consumer's nearest station or wharf in Great Britain. As has hitherto been the case, a certain amount of ordinary quality sulphate, basis 25¼ per cent. ammonia, is available, deliveries of which may be made at the lower figure of £13. 12s. per ton. The bulk of deliveries, henceforward, however, are expected to be of the better quality, which is a most encouraging fact. The pressure brought to bear, and the practical advantages accruing have resulted in a much larger proportion of the make in the United Kingdom reaching the high standard of excellence desired by the Federation. This policy is undoubtedly increasing the confidence and interest of consumers, both at home and abroad, and is the soundest way of strengthening the market for British material. With the value of sulphate, as sold at the new prices, being about 14s. per unit, and taking into account the higher content of nitrogen, the greatly improved mechanical condition, and so on, the price for this fertiliser is now under pre-war figures. Indeed, it is claimed by the Federation that of all the forms of nitrogen now on the market, British sulphate of ammonia is the cheapest. According to the circular, stress is laid on the fact that the quoted price is for material destined to be used for home agricultural purposes only, and contracts are to contain the following stringent, but very necessary clause: "Buyers undertake that the sulphate of ammonia delivered under this contract shall be used for home agricultural consumption in the United Kingdom, Channel Islands, or Isle of Man, and to request an identical undertaking from any buyers to whom they may offer or sell such sulphate; and it is hereby agreed that in respect of every ton of such sulphate sold for export or exported to territory other than the countries named above, whether such sale or exportation shall have been made by buyers themselves, or by buyers' sub-purchasers, or any other sub-purchasers, buyers shall pay to sellers in addition to the purchase price thereof, £10. as and for liquidated damages." With the exception of two items, the allowances and abatements are on the same scale as that prevailing last season. These exceptions are, in the first place, if buyer elects to take delivery ex works by his own vehicle, when an allowance of 5s. per ton is made, compared with 10s. previously. A reduction has also been made, from 12s. 6d. to 10s. per ton on deliveries to fertiliser manufacturers, agricultural merchants, etc. Prices for September delivery will be announced in due course, when it may be anticipated that the Federation's policy of a slowly rising scale of prices will be adopted.

Superphosphate.—British manufacturers have announced their new scale of prices for July delivery, and until further notice. For superphosphate showing 28 per cent., the quotation stands at £3. 2s. 6d. per ton, net, in bags at Liverpool; for 30 per cent., £3. 5s.; 33 per cent., £3. 9s. 6d.; and for 35 per cent., £3. 12s. 6d. The demand at present is generally very slow, very little business passing in any descriptions, with the possible exception of nitrate of soda. The abundant supplies of phosphate rock from Nauru and Ocean Islands which have been reaching Australia have led to the initiation of a scheme for the manufacture of superphosphate on a large scale in Tasmania. Production is to be undertaken by the Electrolytic Zinc Company of Australasia, and they intend to erect a plant with a 50,000-ton capacity. Sulphur is readily available from the zinc concentrates, which contain between 25 and 35 per cent. of the product, and it is estimated that the supply will eventually reach over 30,000 tons. Formerly, some 40,000 or 50,000 tons of sulphur per annum have had to be imported for the manufacture of acid, but this expense is likely to be considerably curtailed. According to the new scheme, therefore, it is expected that something like 45,000 tons of superphosphate can be produced annually.

The UNCHOKEABLE PUMP

NO SCREENS. WILL PASS SOFT OR HARD SOLIDS, INCLUDING SACKING, COTTON WASTE, FIBRE, SLUDGE, PULP, GREASE, COAL, ASHES, COKE, ETC. NO CHOKING.

DEALS EFFECTUALLY WITH ANY MIXTURE THAT CAN ENTER THE SUCTION PIPE.



NO CLEANING. NO HAND LABOUR. NO CUTTING

MADE IN HORIZONTAL, VERTICAL, OR PORTABLE FORM.

SUITABLE FOR CLEARING CESSPOOLS, DYE PITS, VATS, ETC.

Sole Makers:

BLACKSTONE & CO., Ltd.,

STAMFORD.

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS IN MAY.

(Concluded from page 766.)

THE following returns, which are taken from the import statistics of the United Kingdom, give the amount and value of chemicals and allied products imported during the month of May, 1923, compared with 1921 and 1922. As from April 1, 1923, the import trade of the Irish Free State is excluded from the Returns.

Italian Regulations for Colouring Materials.—An Italian Royal Decree recently issued specifies the colouring materials which may or may not be used in the preparation of foodstuffs, toys, soaps, shaving soaps, dentifrices, and cosmetics. A copy and translation of the Decree may be seen by persons interested on application to the Department of Overseas Trade (Tariff Section), 35, Old Queen Street, London, S.W. 1.

REPORTS OF COMPANIES.

Zinc Corporation, Ltd.

At the annual general meeting held in London on Wednesday (June 27), Mr. F. A. Govett, presiding, said: As regards the price of lead, I said last year there was some reason to think that consumption was enlarging, and that therefore the outlook was reasonably good. This has been fairly verified, and I think I may say again to-day that the price is likely to be maintained, with restricted production, considerable American consumption, and a great deal of rebuilding in Europe, which will no doubt continue, so that the outlook for demand seems fairly good. There has been no reduction generally in production costs—in fact, with dearer coal, it has been rather the other way. America has been producing all she can in virtue of the demand for the by-product silver on Government purchases, under the Pittman Act, constituting a sort of bonus with silver at a dollar, contrasted with our market prices. As the purchases under the Act have now ceased, this stimulus on production will disappear, and American lead will again have to compete on even terms. However, altogether I should look for a continued high price. As regards our subsidiary companies, I have not much to say but what is good. The Associated Smelters is as well managed and just as successful as before. The Zinc Producers efficiently handle the business of the zinc, while the Electrolytic Zinc is now producing over 40,000 tons of refined zinc, which will be further increased, and, lastly, the Lead Manufacturers are making satisfactory profits.

British Dyestuffs Corporation, Ltd.

The report for the year ended October 31 last states that the result of the year's transactions, after providing £411,382 for depreciation, and crediting the estimated amount in respect of recovery of excess profits duty, is a profit of £102,656. The balance of loss carried forward from the previous period amounts to £803,355, leaving to be carried forward to the next period a deficit of £700,698. In spite of severe restriction in the manufacture of dyestuffs due to the serious depression in the dye-using industries, and of substantial reductions in selling prices, the trading results of the year showed a marked improvement over those for the previous year. The directors express the opinion that it would be advantageous for administrative purposes to liquidate the associated companies—namely, British Dyestuffs Corporation (Huddersfield), Limited, British Dyestuffs Corporation (Blackley), Limited, and Claus and Co., Limited, and to transfer their undertakings to British Dyestuffs Corporation, Limited, which would then become the sole owning and operating company.

British Oxygen Co., Ltd.

Report for the year ended March 31, 1923, states that after providing for debenture interest and redemption, depreciation and usual standing charges, profit amounted to £131,800. Directors propose to place £25,378. to general reserve, bringing total to £150,000. Remaining balance is £106,422. Final dividend, free of tax, at the rate of 1s. 9d. per share (absorbing £40,312.), making, with the interim dividend of 9d. per share, free of tax, paid in December last, for the year 2s. 6d. per share, equivalent to 12½ per cent., free of tax, upon whole issued capital.

W. J. Bush and Co., Ltd.

Accounts for 1922 show a gross profit of £245,940., and a net profit of £41,788. Adding £2,658. brought in, after adjustment of E.P.D., corporation profits tax, and income tax, there is a balance of £44,446. Directors recommend final dividend of 5 per cent. on ordinary shares, making 8 per cent. for year. Forward, £18,197.

New Transvaal Chemical Co., Ltd.

Report for year to June 30, 1922. shows that the balance standing to credit of profit and loss, including £6,254. brought forward, is £83,290. Directors have transferred to depreciation account, £10,570., leaving £72,720., out of which dividends on preference shares absorbed £24,000. Directors recommend payment of the remuneration of the London board, £630., dividend of 15 per cent. on ordinary shares, £37,500; forward, £10,590.

DIVIDENDS.

Dominion Tar and Chemical Co., Ltd.—Interim dividend of 2½ per cent., free of tax.

Mond Nickel Co., Ltd.—Final dividend of 7½ per cent., free of tax, on the ordinary shares, making 10 per cent. for the year ended April 30. The dividend a year ago was 5 per cent., making 7½ per cent. for the year, free of tax.

Briton Ferry Chemical and Manure Co., Ltd.—Dividend announced on 7 per cent. cumulative preference shares for the completion of the payment of arrears of dividend to December 31 last and six months' interim dividend to June 30.

Welsbach Light Co., Ltd.—Dividend of 5 per cent. actual (1s. per share) and a bonus of 2½ per cent. actual (6d. per share), both less income tax.

Broken Hill South Mining Company, Ltd.—Dividend of 1s. 6d. per share.

GAZETTE NEWS.

MORTGAGES AND CHARGES.

Booshu Manufacturing Co., Ltd., London, E.C., polish manufacturers.—Reg. June 5, £1,250. deb., to E. V. F. R. Dugmore, 11, St. Marks-rd., Alverstoke.

BANKRUPTCY INFORMATION.

Fishwick, Albt. Baden-Powell, 4, North-rd., Longsight, Manchester, trading as Brown and Co. soap manufacturers. 1st and final, 1/4, at O.R.'s, Manchester, July 2.

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

Teague, Wm., 46, Olive-la., Darwen; paint manufacturer; £23. 13s. 4d. May 11.

Ajax Manufacturing Co., Ltd., 62a, Loughborough-rd., Brixton; paint manufacturers; £13. 13s. 10d. April 19.

South Wales Colliery and Shipping Supply Co., oil and grease manufacturers; £10. 4s. 11d. April 27.

NEW COMPANIES.

Burbanks (Pilbarra) Copper Mines, Ltd. Capital £150,000., 5s. shares. Agreement with Burbanks Birthday Gold Mines, Ltd., and E. C. C. Smith, the lidr. thereof. Secretary: E. C. C. Smith, 20, Bucklersbury, E.C.

Cement Supply Co., Ltd.—Private company. Capital £2,000. £1. shares (1,950 A. and 50 B. Manufacturers of and dealers in cement, etc. Office: Westminster Chambers, 3, Victoria Street, S.W. 1.

Crampshaw, Ltd.—Private company. Capital £500. Manufacturers of and dealers in all kinds of carbolic, creosotic and other disinfecting fluids and powders, etc. Secretary: E. Cadogan, Imperial Buildings, Mount Stuart Square, Cardiff.

Industrial Residues, Ltd.—Private company. Capital £100. Dealers in residual products, etc. Secretary: A. Clayfield, 10, Upper Priory, Birmingham.

Pike, Laggett and Cash, Ltd.—Private company. Capital £5,000. Glass manufacturers and merchants, etc. Office: Chatham Place Glass Works, Hackney, E. 9.

Treamble Minerals, Ltd.—Private company. Capital £20,000. Office: Exchange Buildings, Station Road, Port Talbot.

Waterhouse and Gray, Ltd.—Private company. Capital £1,000. Manufacturing chemists and wholesale druggists, etc. Office, 52, Stanley Street, Sheffield.

Windsor Richards Protective Paint Co., Ltd.—Private company. Capital £1,000. Office: 104, High Holborn, W.C.

George O'Malley, Ltd.—Private company. Capital £1,000. Wholesale and retail dispensing chemists. Office: Main Street, Mohill, Co. Leitrim.

Klenso, Ltd.—Private company. Capital £5,000. Manufacturers of soaps, soap powders, etc. Solicitor: C. J. Murray, 30, Parliament Street, Dublin.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

June 18 to 23 (inclusive).

Treating Tar for Roadmaking. Aeberli, H. 16,376.
Centrifugal Separators. Aktiebolaget Separator. 16,010 and 16,026.
Diastases and Toxines. Boidin, A.; and Effront, J. 15,797.
Substances Containing a Methyl Radicle. Calvert, G. 15,932.
Adhesives. Coffey, A. J. 16,111.
Viscose Silk. Dreaper, W. P. 16,196.
Aliphatic Derivatives. Dreyfus, H. 16,263.
Polymerisation Products of Acetylene. Elektrizitätswerk Lonza. 16,283.
Colouring Fibrous Materials. Gentner, C. 16,134.
Adhesive for Rubber, Leather, etc. Hallett, G. 15,768.
Insecticides. Howles, F.; and McDougall, I. 16,371.
Heating Coal. Ilingworth Carbonisation Co., Ltd.; and Illingworth, S. R. 16,272.
Calorimeters. McAlpine, G. L. 15,948.
Vulcanising Oils or Fats. Meulen, J. H. van der. 16,164.
Autoclaves. Mycock, W. 16,214.
Scrubbing and Washing Gases. Nielsen, H. 16,167.
Aluminium Paint. Ormiston, C. P. 16,287.
Separating Materials of different specific gravity. Peale, R. 16,155, 16,156, 16,157, and 16,158.
Detonating Explosives. Staudinger, H. 16,165.
Solutions of Metal-iodide-alkali-iodide Compounds. Truttwin, H. 15,876.
Cellulose Acetates. Zdanowich, J. O. 15,781.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 1s. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.

1921.

Concentration of Ores and Minerals. Marks, E. C. R. (*Eureka Metallurgical Co.*). 33,254. **199,051**
Apparatus for Chlorine Control. Meter, J. W. van. 33,359. **199,052**
Extraction of Oils from Fish. Mitsui, K.; and Takahashi, C. 33,425. **199,054**
Cement. Rigby, T. 34,126. **199,056**

1922.

Vulcanising Rubber. Naugatuck Chemical Co. 931. **174,915**
Chlorination of Montan Wax. Jennings, H. W. K. (*Stinnes, H., firm of*). 4,581. **199,073**
New Aromatic Carbonyl Compounds Containing Trivalent Arsenic. Margulies, Dr. O. 7,119. **199,091**
New Derivatives of Organic Arsenic Compounds. Margulies, Dr. O. 7,120. **199,092**
New Arsenoxides and Arsenobenzols. Margulies, Dr. O. 7,144. **199,093**
Sulphurous Acid Compounds of Isatinanilide or Arylides. Stephan, Dr. C. 8,059. **199,154**
Chlorination of Cellulose Lyes. Schmidt, Dr. A. 9,323. **178,104**
Lubricating Oils. Eichwald, E.; Vogel, H.; and Hardt, P. 9,697. **178,113**
Evaporating, Distilling, Heating, or Cooling Fluids. Blair Campbell and McLean, Ltd.; and Blair, A. 12,592. **199,210**
Esters and Ethers of Ethylidene-glycol and Vinyl Alcohol. Consortium für Elektrochemische Industrie Ges. 16,898. **182,112**
Methane. Farbwerke vorm. Meister, Lucius, and Brüning. 23,561. **186,899**
Magnesium Carbonate from Magnesium Carbonates and Magnesium Silicates Containing Calcium. Hambloch, Dr. A. 33,798. **194,663**
Hydroxylated Aliphatic Arsinic Acids. Etablissements Poulenc Frères; and Oechslin, C. 34,890. **191,028**
Acetone from Acetylene. Elektrizitätswerk Lonza. 2,200 **192,392**

COMPLETE SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

1923.

Asbesto-cement Compositions. Lanhoffer, I. E.; and Lanhoffer, O. E. 139. **199,350**
Diphenylguanidine. Naugatuck Chemical Co. 9,369. **199,354**
New Dyestuffs of Indigo Tint. Society of Chemical Industry in Basle. 11,431. **199,360**
Hydrogen. L'Oxhydrique Française. 11,651. **199,364**
Dioxyperylene. Pereira, H. 15,642. **199,401**

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Fumigants. J. E. Evans-Jackson, London. (Deutsche Gesellschaft für Schädlingsbekämpfung, Frankfort-on-Maine, Germany.) British Patent, **196,524**, of 1922.

In fumigating for the destruction of insects the gaseous or volatile poisonous substance employed is hydrocyanic acid or a cyano-carbonic ester such as the ethyl or methyl esters, and to this is added a halogen acid ester, such as methyl chloro-carbonic acid ester or a bromo-acetic acid ester, a haloketone, or a halogen xylol, any of which are strongly irritating to the respiratory organs, so that escape of the vapours may be readily detected.

Filter-presses. S. R. Jackson, Hanley; A. E. Jackson, Baddeley Green; and T. D. Jackson, Birches Head; all in Stoke-on-Trent. British Patent, **193,654**, of 1922.

Metal plates for filter-presses are formed with a surround having pockets or cavities, the walls of which are equal in thickness to the other parts of the plate, so that contraction due to cooling is uniform throughout.

Colloidal Antimony Sulphides. M. E. Wolvekamp, Oakland, California, U.S.A. British Patent, **197,061**, of 1922.

Stable, colloidal antimony tri and penta sulphides associated with a salt of a protein are prepared by redissolving in alkali the product obtained by precipitating an alkaline solution of a sulphantimonite or of a sulphantimonate with excess acid. In examples colloidal antimony trisulphide is obtained from a solution containing tartar emetic, sodium sulphide, and sodium protalbinate, and colloidal antimony penta sulphide is obtained from a solution containing Schlippe's salt and sodium protalbinate. The solution of the precipitate obtained by adding sulphuric acid is redissolved in caustic soda and evaporated at 100° C. to dryness. Alternatively the solid product may be obtained by adding hydrochloric acid and alcohol to the alkaline solution of the sulphantimonite or sulphantimonate.

Sodium Chromate. E. Baumgartner, Roskilde, Denmark. British Patent, **197,223**, of 1922.

Sodium chromate is obtained by heating in a current of hot air in a muffle, a mixture of chromium ore with sodium carbonate with or without lime or calcium carbonate. The materials are formed into briquettes and are arranged in the muffle, for instance in rows with spaces between so as to allow contact with the current of air. Stirring or turning of the charge is unnecessary and undesirable and the operation is complete in one burning.

Sodium Hydroxide. Courtaulds, Ltd., and R. O. Jones, both in London. British Patent, **197,198**, of 1922.

Solutions of sodium hydroxide obtained by causticising strong solutions of sodium carbonate with lime and filtering are concentrated by cooling to between 0° and minus 15° C. to remove the sodium carbonate as decahydrate. In this way solutions containing 15 to 25 per cent. sodium hydroxide and not more than 1 per cent. sodium carbonate may be obtained. Instead of causticising in the usual manner the process described in Specification 182,661 may be used.

Sulphurised Dyestuffs. F. W. Atack, Manchester. British Patent, **196,993**, of 1922.

Indophenolic bodies are sulphurised by treatment with a polysulphide in presence of normal butyl alcohol as solvent. The indophenol may be used dry or in the form of a wet paste. In an example the indophenol from carbazol and *p*-nitroso-phenol is treated with sodium sulphide and sulphur in presence of butyl alcohol at 100° C. and under a reflux for 50 hours. The resulting mixture is diluted with water and the dyestuff separated in the usual manner. It is stated that pyridine may be used in admixture with the normal butyl alcohol. According to the Provisional Specification organic compounds in general may be sulphurised as described above and pyridine alone or other inert liquid of similar boiling-point may be employed as a solvent.

Powdered Lead. G. Shimadzu, Kyoto, Japan. British Patent, **197,031**, of 1922.

A chemically-reactive fine lead or other metal powder is produced by rotating a vessel charged with lead balls or pieces of metal so as to cause abrasion of the balls or pieces between each other and the inner surface of the vessel. Hard metal balls may be introduced into the vessel with the pieces of lead. A hollow cylindrical iron vessel with feed and discharge openings at its ends may be used. An air blast from a blower within the vessel blows the fine

powder out of the discharge opening into a collecting-chamber; or the vessel may be pierced all over with small holes through which the fine powder is blown out. Instead of air, dry carbonic-acid gas, nitrogen, etc., may be used to discharge the metal powder from the hollow cylinder, and the velocity of the air or other gas may be regulated to determine the fineness of the powder removed from the cylinder.

Catalytic Materials. L. Casale, Rome. British Patent, **197,199**, of 1922.

A catalytic material is prepared by injecting oxygen under pressure into heated iron or an alloy of iron with manganese, chromium, molybdenum, tungsten, carbon and the like, until the mass is brought into a state of violent ebullition and part of the oxidation product is vapourised away. Any impurities present in the starting material which are detrimental to catalysis are thereby eliminated. The cooled product may be reduced to the metallic state with hydrogen or nitrogen-hydrogen mixture. The catalysts are for use more particularly in the synthesis of ammonia, but may be employed for other catalytic operations such as the oxidation of ammonia to nitric acid or of carbon monoxide to carbon dioxide, or for the production of hydrogen from water and carbon monoxide. The proces may also be applied to the regeneration of iron or iron alloys whose catalytic efficiency has become impaired. According to the example, oxygen is forced through a hole in the bottom of a magnesia crucible containing turnings of impure iron or molybendum steel together with lime, the turnings being heated to a temperature below that of fusion; the reaction proceeds with almost explosive violence and is stopped when 5 to 15 per cent. of the oxidation product has been eliminated by the excess of oxygen; on cooling, the resulting iron oxide is crushed and either used as such or reduced to the metal.

Dyeing Cellulose Ethers. H. Dreyfus, London. British Patents, **196,952, 196,953, 196,954,** and **197,281,** of 1921.

Insoluble cellulose ethers in thread, film, fabric, or other form, or mixed goods containing them, are dyed or printed with acid dyes or direct cotton dyes. The dyes may be dyed on mordants, or be after-chromed or treated with copper salts, etc. In examples, ethyl cellulose silk is dyed with congo red, diazo fast black, nigrosine B, alizarine astrol B. azo yellow 3G, rocelline, and orange 11. Specification 182,830 is referred to. They are also dyed or printed with basic dyes. Mordants may be employed, or the dyeings may be after-treated by known methods. In an example, ethyl cellulose silk is dyed in a bath containing acetic acid with the following dyes:—Magenta, malachite green, rhoduline red B, methyl violet O, auramine O, saffranine T, thioflavine T, or methylene blue B. They are also dyed by forming azo dyes on the material or by forming thereon aniline blacks, paramine browns, and the like by oxidation of aromatic bases. In examples, Paranitraniline red and aniline black are formed on ethyl cellulose silk. They may also be dyed with vat dyes. In an example, ethyl cellulose silk is dyed with indigo in a hydrosulphite vat; anthraquinone vat dyes are also specified as suitable.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Halogen - Substituted Hydrocarbons. Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst-on-Main, Germany. British Patent, **196,272.** Convention date, April 15, 1922.

Halogen-substituted hydrocarbons or mixtures thereof are converted with elimination of hydrochloric acid into hydrocarbons or other halogen-substituted hydrocarbons containing a higher number of carbon atoms by conducting them, in admixture with water, over certain catalysts at a raised temperature not exceeding 400° C. The catalysts comprise metals, certain non-metals, and metallic compounds, such as ThO_2, $ZrCl_4$, Bi_2O_3, $SnCl_4$ and $ZnCl_2$, and are mounted on porous materials, particularly highly-active charcoal. Pressures higher than atmospheric may be employed. According to an example, methyl chloride and traces of water are passed through a tube containing finely-divided platinum mounted on a carrier and maintained at a temperature of 275° C.; the product, comprising ethyl chloride, unchanged methyl chloride and hydrochloric acid, is washed to remove the acid and the gaseous chlorides are separated either by the use of an absorbent, such as highly-active charcoal, or by liquefaction and fractional distillation of the mixture.

Refining Tin. T. Goldschmidt Akt.-Ges., L. Schertel, and W. Lüty, Essen, Germany. British Patent, **196,938.** Convention date, April 29, 1922.

Tin is refined by removing impurities, such as arsenic, antimony, and copper, in a scum produced by adding to a bath of molten tin an element, such as sodium, calcium, zinc, or aluminium, and then bringing the bath into contact with an oxygen-containing substance, such as air or water. The elements may be added in instalments, and the scum removed after each addition, and the elements may be added separately or together such as in the form of an alloy. The scum obtained in one refining operation may be used for the treatment of further quantities of tin, and when the absorptive capacity of the scum is sufficiently reduced, any tin present may be separated by a liquidation process, and the elements recovered in any known way.

Synthetic Resins. Holzverkohlungs-Industrie Akt.-Ges., Konstanz, Baden, Germany. British Patent, **196,265.** Convention date, April 11, 1922.

Resins are obtained by the interaction of aromatic hydroxy compounds, such as phenols and naphthols, with methylene chloride in the presence of ammonia or of substances which produce ammonia. Usually two or more molecules of ammonia are employed for each molecule of methylene chloride. Other bases, such as sodium hydroxide, may be added to facilitate the reaction. According to an example, phenol is heated for some hours with methylene chloride and aqueous ammonia at a temperature of 150° C., a yellow resinous product being obtained.

Coating Aluminium. Aluminium Company of America, Pittsburg, U.S.A. (Assignees of A. Pacz, East Cleveland, Ohio, U.S.A.) British Patent, **195,625.** Convention date, April 3, 1922.

Aluminium is alloyed with at least 4 per cent. of silicon, and the alloy is treated so as to form on its surface a layer of silicon which resists corrosion, forms a basis for paint, electro-plating depositions, etc., and also serves as a self-lubricating bearing material. In the treating process, which is termed "silurising," the alloy is pickled in either acid or alkali solutions, or both, and then subjected to the action of aqua ammonia at about 50-80° C. If the article is free from grease the pickling may be omitted. Articles to be electro-plated need not be treated with ammonia.

Alkali and Alumina from Leucite. F. Jourdan, Rome. British Patent, **195,084.** Convention date, March 16, 1922.

Leucite or other rock containing alkali and aluminium silicate is fused with lime or calcium carbonate and the product is pulverised and extracted with water, a solution of alkali aluminate being obtained. Carbonic acid, which may be obtained by calcining limestone, is then passed into the solution to obtain alumina and alkali carbonate. The lime and leucite may be mixed in the proportion of 70 to 120 parts of lime to 100 parts of leucite, and the mixture may be made into small briquettes. The heating may be effected in a kiln or rotary furnace, the temperature being 1000-1400° C.

Azo Dyestuffs. Farbwerke vorm. Meister, Lucius and Brüning, Hoechst-on-Main, Germany. British Patent, **193,883.** Convention date, February 24, 1922.

Azo dyes are obtained, either in substance or on the fibre, by coupling diazo compounds with a *p*-toluidide, a *p*-alkyloxyanilide, a *p*-aryloxyanilide, or a *p*-arylkyloxyanilide of 2:3-oxynaphthoic acid, in which the arylido group contains halogen as substituent. The shades obtained on the fibre are fast to kier-boiling, especially those derived from halogenated diazo components. An example is given in which diazotised 6-nitro-2-toluidine is printed on material padded with 2 : 3-oxynaphthoic-chlortoluidide (NH : Cl : CH_3 = 1 : 2 : 4).

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

The slump in the hematite pig-iron trade, which has resulted in a marked diminution in production in the Furness district, had not affected West Cumberland in mid-week, and the whole of the production of coke was still going into consumption. It looks as though there also, however, furnaces will have to be damped down and in that case, of course, the coking plants will be unable to work at normal pressure. The bottom seems to have fallen out of the iron trade, and it is significant that Bessemer mixed numbers were stated to be only nominally at last week's quotation of £6. 5s. delivered at Glasgow and Sheffield. Less than this figure is being accepted to obtain any business that is moving, and there was no concealment of the fact that the accumulation of stocks of iron may force makers to curtail their production. The unfavourable developments of the last few weeks are attributed to the unrest on the Continent, and it becomes increasingly certain that there can be little if any improvement in the outlook until the reparations problem is in a fair way to settlement. As yet neither the coal nor coke trade has become seriously involved in the depression in the iron trade. All the coal being raised finds a ready market, though it is not to be forgotten that as the dispute at the Whitehaven collieries still drags on, the production is appreciably lower. There is rather more coal at command for shipment since there has been a seasonal decline in local house needs, and rather less coal is wanted for the iron ore industry, nearly all the privately-owned mines having closed down. Coke production likewise is diminished, but even so makers now are able to supply some Scotch needs which have arisen. Nothing is being done in the Continental market. Local smelters are paying 24s to 30s. per ton for the local coke, according to carbon content. For the first time for many months there have been no imports of East Coast coke into the district, and the supplies to the Furness district this week have fallen from 13,500 tons to 7,500 tons. By-products are a middling market, and road tar is in good demand. Creosote is in fair request, and tar acids are a moderate trade.

PUBLICATIONS RECEIVED.

Department of Overseas Trade Reports.—Obtainable from H.M. Stationery Office. **Denmark** (to March, 1923). By Mr. R. M. Turner, Commercial Secretary to the British Legation, Copenhagen. Price, 1s. 6d. net. **Serb-Croat-Slovene Kingdom** (Jugoslavia), to April 1923. By Captain E. Murray Harvey, O.B.E., M.C., Commercial Secretary to H.M. Legation, Belgrade, 1923.

THIRTY-FIVE YEARS AGO.

(From the "Chemical Trade Journal," July 7, 1888.)

Technical Instruction.—If we had to draw the line between chemists and chemists, we would say that the man who was simply kept in the laboratory to test drugs should be placed on the lower side of that line, and it is a question whether a lad from a Board School would not do quite as well as a more highly-trained man. Our own opinion is that wherever the employer or responsible manager is not truly a chemical expert, the deficiency should be supplied by the appointment of a first-rate man as superintendent, who should have a position co-equal with the manager. And in cases also where the employer does not himself personally superintend, but is yet a good chemist, the presence of another good chemist is none the less essential, seeing that the constant supervision of chemical processes is absolutely necessary. We have laid much stress on the desirability of securing the services of a good chemist, a man of originality of thought and of thorough devotion to his work, and may not improbably be asked the question: Supposing a manufacturer be willing to pay a fair salary, what guarantee has he that he is securing the services of the right man? We cannot answer the question. Chemists are not "hall marked"; there is no royal road to any method of differentiation, and we fear there is no other way than to take him at his own estimate until the contrary has been proved.

MARKET REPORTS.

LONDON "OPEN MARKET" REPORT.

Wednesday.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals.—The poor state of business generally is now very marked. Almost without exception, industrial chemicals seem to be of no interest to the usual buyers at home or to foreign purchasers. What little buying there is about is invariably for the smallest possible quantity, with the price cut to a minimum No one—neither buyer nor seller—shows the slightest confidence. It seems an undeniable fact that the long-drawn-out political unrest in Europe generally, and the Franco-Belgian occupation of Germany, are gradually bringing commerce to a complete standstill. A settlement of the various disputes on almost any basis would seem preferable to the present position. **Acetic Acid** keeps steady at old rates—there is little about on spot; inquiry has been much slower of late; 80% technical, £47.; 80% pure, about £50.; 98% glacial, £60. in casks and £75. in glass demijohns, ex wharf, London. **Acetone,** British Government specification, about £120. per ton; this is the quoted rate, and the market seems quite firm, with supplies very short. **Arsenic,** Cornish, white powdered, about £71. to £72. per ton; these prices are asked for a few small spot parcels on the market; very little demand. **Alum,** lump, in casks, £10. 10s. per ton; dealers continue to quote at this rate, but find very little interest shown. **Anhydrous Ammonia,** 99-95%, 1s. 5d. to 1s. 6d. per lb.; dealers are offering at slightly cheaper rates, with the market dull. **Barium Chloride,** 98-100%, £15. to £15. 10s. per ton; the market has moved in buyers' favour—business has been very poor. **Bleaching Powder,** 35-37%, £10. to £10s. 10s. per ton; dealers are offering at these rates with little doing. **Borax,**

commercial, granulated, £26. 10s.; crystal, £27.; powder, £28.; extra fine, £29.; B.P., crystals, £31.; powder, £32.; extra fine, £33. per ton, for home trade only, in free 2cwt. bags, carriage paid to destination. British makers continue to offer at these rates. Importers are offering under similar conditions commercial granulated at £25. 10s., and powdered £27. per ton. **Borax Glass,** lump, £74.; powdered, £75. per ton, in tin-lined cases; British makers' prices are at these levels. **Boric Acid,** commercial, crystals, £50.; powdered, £52.; B.P., crystals, £56.; powdered, £60.; extra fine, £62.; in bags free, carriage paid to destination; British makers continue to offer at these prices; dealers are quoting at very competitive rates. **Cream of Tartar,** 99-100%, 92s. to 94s. per cwt., less 2½%; this market has shown a little business, and prices as quoted seem steady. **Citric Acid,** B.P., crystals, about 1s. 9d. per lb., less 5%; spot offers for small lots are at about this price, but there has not been much business about. **Epsom Salts,** commercial quality, about £5. per ton, in bags; the demand is still very poor—dealers offering at this price. **Formaldehyde,** 40% volume, about £95. per ton, nominal; there are little, if any, stocks on spot, and buying is not taking place; the market is likely to remain idle until the referee's decision in the appeal case is issued; the hearing has been completed. **Glauber's Salt,** commercial quality, about £3. 15s. to £4. per ton, in bags; this market is particularly quiet—quoted rates unchanged. **Lead Acetate,** brown, about £42.; white crystals, about £43. to £44. per ton; slightly easier rates are quoted this week, with the market dull. **Litharge,** pure flake, British, about £37. per ton; imported is offering by dealers at about £35. to £35. 10s. per ton; not much doing. **Lithopone,** 30% Continental red seal, about £22. 10s. per ton; this market keeps fairly steady, and some limited business continues. **Ammonium Chloride,** grey galvanising, about £30. 10s. per ton; plenty of material available on spot at this rate, but the demand is small. **Nickel Sulphate,** home trade, single and double salts, £38. per ton, delivered; export, single and double salts, £38. per ton, f.o.b.; British makers quote at these rates. **Oxalic Acid,** about 6d. to 6¼d. per lb., as to quantity; this market remains very dull—prices are unchanged. **Bichromate of Potash,** about 6d. per lb.; this market, so far as dealers are concerned, shows but little life. **Carbonate of Potash,** 90-92%, about £29. per ton; 96-98%, about £32. per ton; the demand remains poor—spot stocks available. **Chlorate of Potash,** crystals and granular, about 3d. per lb.; business has been quiet—quoted rates are easy. **Caustic Potash,** 88—92%, about £33. 10s. per ton; dealers in imported material are quoting at about this figure—there has been little doing. **Permanganate of Potash,** about 10d. per lb.; this market is easier this week and prices are irregular—business has been quiet. **Prussiate of Potash,** yellow, about 1s. 3¼d. to 1s. 3½d. per lb.; dealers are offering at cheaper rates once more this week, but business is still lacking. **Sulphate of Potash,** 90%, £11. 10s. per ton, ex ship; the market shows no change on the week. **Mercury,** about £11. per bottle of 75—76lb. net; prices are about the same, with business rather quiet. **Red Lead,** imported, about £35. 10s. per ton, c.i.f., London; this market remains dull—quoted rates are steady. **Salammoniac,** dog-tooth crystals, £49. to £50.; medium, £43. to £44.; fine white crystals, £27. to £28. per ton; there has been but very little inquiry for the spot supplies on offer—quoted rates from dealers are unchanged. **Saltcake,** ground and unground, home trade, about £5. per ton; export, £5. 5s. to £5. 10s. ton, f.o.b.; some inquiry continues. **Acetate of Soda,** about £25. per ton; dealers are quoting at this level for forward delivery. **Soda Ash,** 58% light alkali, £7. 12s. 6d. per ton, in bags, carriage paid in the United Kingdom; this price is quoted by British makers for home consumers only. **Soda Crystals,** £5. 5s. per ton, in bags, carriage paid to destination; British makers selling at about this figure for home trade only; dealers are offering at competitive rates. **Caustic Soda,** 70—72%, £19. 10s.; 76—77%, £21. 10s. per ton, in drums, ex wharf, shipping port; dealers continue to quote at about these prices, but are finding but little business. British makers' prices for home trade only are unchanged at from £19 to £21. 10s. per ton, in drums, carriage paid. American material is offering c.i.f. Continent at competitive prices. **Bicarbonate of Soda,** £10. 10s. per ton, in bags, carriage paid to destination; British makers offering for home trade only at this price. **Chlorate of Soda,** crystals and granular, 2⅞d. per lb.; spot business remains quiet—quoted rates are easy. **Cyanide of Soda,** 98—100%, 8½d. to 9d. per lb., for export. Home trade, about 11d. per lb.; British makers' prices are quoted. **Nitrate of Soda,** 96%, £13. 7s. 6d. per ton, f.o.r. Liverpool; quoted prices are level on the week, with the market steady. Nitrite of Soda, 100%, about £27. per ton; the market shows no change on the week. **Prussiate of Soda,** about 7d. per lb.; offers are plentiful, but business remains very slow, and the market is not at all steady. **Hyposulphite of Soda,** pea crystals, about £15. 10s. per ton, in 1cwt. kegs; commercial quality, about £10. 10s. per ton, in casks; dealers have been doing some little business and their prices seem fairly steady. **Sodium Sulphide,** 60—62% solid, £14. to £14. 10s. per ton; broken, £15. to £15. 10s. per ton, in drums; 60—62% concentrated, £15. per ton, in casks; dealers are offering at cheaper rates, but find business still very difficult. **Sulphate of Copper,** about £26. to £26. 10s. per ton; prices are a little cheaper this week—business has been limited. **Tin Crystals,** 1s. 4d. per lb.; the market is unchanged on the week. **White Lead,** imported, about £43. to £44. per ton; dealers are doing some small business in imported material at about these figures. **Zinc Oxide,** B.P., about £52.; white seal, about £44.; 99.5%, about £37. per ton, f.o.r. makers' works; British makers continue to offer at about these levels, with very little doing.

Pharmaceutical Chemicals.—From all quarters reports on the past week's business are very depressing. A state approaching stagnation seems to have been reached in many items. Prices in a large number of products are quoted at cheaper rates this week. **Acetanilid,** crystals and powder, about 1s. 6d. per lb.; this article is now being offered at cheaper rates—market quiet. **Acetyl-Salicylic Acid,** B.P., about 3s. 1d. per lb.; the market has moved in buyers' favour and business has been much slower. **Benzoic Acid,** B.P., about 2s. 6d. per lb.; there has been but little inquiry on the market. **Diethylbarbituric Acid,** B.P. (barbitone), about 21s. per lb.; this unchanged rate is quoted by dealers, but there is little business about. **Salicylic Acid,** B.P., about 2s. 3d. per lb.; this market has been quiet and prices are not any too steady. **Tannic Acid,** leviss, about 3s. 6d. per lb.; this market keeps fairly steady, but business is lacking. **Amidopyrin,** about 14s. per lb.; slightly easier rates are being quoted here, with business dull. **Ammonium Bromide,** about 7¾d. to 8¼d. per lb.; cheaper offers are being made, but the demand is very poor. **Benzonaphthol,** about 5s. per lb.; quoted nominal on an idle market. **Benzaldehyde 03,** about 3s. per lb.; the spot position is unchanged, with little doing. **Beta-naphthol,** resublimed, about 1s. 10d. per lb.; this market seems steady, but remains on the quiet side. **Calcium Lactate,** about 1s. 10d. to 2s. per lb.; some cheaper offers have been on the market, which is still quiet. **Chloral Hydrate,** duty paid, 4s. to 4s. 3d. per lb.; these rates are maintained by spot holders. **Creosote,** B.P., about 2s. 2d. per lb.; there has been no improvement in business. **Creosote Carbonate,** about 8s. 6d. per lb.; this unaltered price is asked by dealers, who find business very quiet. **Guaiacol Carbonate,** about 8s. 3d. per lb.; the market remains neglected. **Hexamine,** about 4s. per lb.; there is a slightly easier tendency in this product, and business has been much quieter. **Hydroquinone,** 3s. 8d. to 3s. 9d. per lb.; there has been some little business about—prices seem steady. **Methyl Salicylate,** about 2s. 6d. per lb.; the tone of the market is not so good this week—business very small. **Methyl Sulphonal,** about 15s. per lb.; there is still no interest shown in this product. **Paraformaldehyde,** about 3s. 9d. per lb.; this price is so far maintained, but the market is dull. **Paraldehyde,** about 1s. 5d. per lb.; easier prices are being quoted this week, but there are few buyers about. **Phenacetin,** about 6s. 6d. per lb.; spot holders continue to quote at about this rate, but find business much quieter. **Phenazone,** about 7s. 6d. per lb.; the quoted rate is maintained, with the market flat. **Phenolpthalein,** about 6s. 3d. per lb.; Continental rates are still firm, and the spot position keeps in line. **Piperazine,** about 3s. 6d. per oz., in kilo. lots; there is still but little inquiry about for the spot supplies available. **Potassium Bromide,** B.P., crystals and granular, 6¾d. to 7d. per lb.; this market, with the other bromides, has moved in buyers' favour and there seems to be little demand for the plentiful offers about. **Potassium Permanganate,** B.P., about 10½d. per lb.; the market has moved to this easier rate, and business is quieter. **Potassium Sulphoguaiacolate,** about 5s. 6d. per lb.; this market remains idle—quoted rates unaltered. **Salol,** about 2s. 9d. per lb.; there is a somewhat easier tone here, and the demand has been much lighter. **Sodium Benzoate,** about 2s. 6d. per lb.; no movement reported—quoted un-

changed. **Sodium Bromide**, crystals and granular, 7½d. to 8d. per lb.; offers for spot supplies and for shipment from the Continent are easier this week; business is very poor. **Sodium Diethylbarbiturate**, about 18s. 6d. per lb.; no business recorded. **Sodium Salicylate**, powder, about 2s. 5d.; crystals, about 2s. 7d. per lb.; prices are a shade cheaper this week, and business has dropped off. **Sulphonal**, about 15s. per lb.; little interest shown in offers at about this rate. **Terpin Hydrate**, about 1s. 9d. per lb.; this market is fairly steady, but quiet. **Thymol**, about 15s. per lb.; offers at this rate, with buyers scarce.

Coal-tar Products, Intermediates, Etc.—Pitch is nominal on spot, but fair business is being done for forward delivery at firmer rates. Carbolic acid crystals are again cheaper. Naphtha is also lower. Other products show no material change. The market generally is extremely quiet. **Aniline Oil**, 9½d. to 10d. per lb., drums free; last week's easier price is still quoted, with business lacking. **Aniline Salt**, 9½d. to 10d. per lb., casks free; there has been no further alteration in the quoted price. **Betanaphthol**, about 1s. 1d. to 1s. 2d. per lb.; business remains very quiet—quoted rates are easy. **Benzol**, 1s. 7d. per gallon, f.o.r. makers' works, in buyers' packages; quoted rates are unchanged—business very poor. **Toluol**, 2s. per gallon, f.o.r. makers' works, in buyers' packages; the demand remains slow—quoted price shows no change. **Xylol**, pure, 2s. 3d.; commercial, 1s. 6d. per gallon, drums extra; there has been no improvement in business—prices are unaltered. **Naphtha**, about 1s. 5d. per gallon; a further depreciation is recorded and business is still very unsatisfactory. **Solvent Naphtha**, 90—160, 1s. 5d. per gallon, drums extra; the market has been dull—no change in price. **Heavy Solvent Naphtha**, 90—190, 1s. 4d. per gallon, drums extra; the market has been almost idle—quoted rates unchanged. **Special Oil**, for Diesels and motors, 10d. per gallon, barrels free; this product is seldom called for—quoted as last week. **Burning Oil**, crude, No. 3, 8½d.; No. 2, 8d. per gallon, barrels free; there has been very little demand of late—prices are unaltered. **Creosote Oil**, 10d. per gallon, naked f.o.b.; this market holds steady, but has been quieter during the past week. **Carbolic Acid**, crystals, about 1s. 2d. per lb.; a sharp drop in price has taken place and the market remains very flat. **Naphthalene**, about £20. per ton; market steady, but dull; crude, £7. to £13.; crystals, £21.; powdered, £17. 10s.; balls, £24.; tablets, £28.; candles, £28. per ton, packages free. **Disinfectants**, 3s. 9d. per gallon, barrels free; this old rate continues to be quoted, with the demand small. **Pyridine**, 18s. per gallon; the spot market has practically nothing to offer—prices as quoted are very firm. **Hexamethylene**, 4s. to 4s. 3d. per gallon; this market keeps very steady at these rates. **Pure Methyl Alcohol**, £100. per ton, ex wharf, London; spot stocks are still restricted—quoted prices from dealers are firm. **Pitch**, 132s. 6d. per ton, spot London, nominal; no business reported; 145s. is quoted for forward positions, and a fair volume of business is said to have been done.

ITALIAN CHEMICAL MARKET.

Genoa, June 30.

Notwithstanding the considerable rise in the value of the English pound, the smaller demand for industrial chemicals caused a reduction in prices of most products. The activity in the soap and cotton industries, however, together with the higher lire quotations, increased the price of caustic soda. The sulphur position was much better, the demand being of larger dimensions. It is probable that the reduction of stocks will lead to higher prices in the near future. Quotations during the month were as follows, prices being per 100 kilos. at Milan, unless otherwise stated:—**Caustic Soda**, 70-72%, Italian, 185 lire; American, 76-78%, 210 lire; English, 190 lire; French, 190 lire. **Carbonate of Soda**, 98-100%, Italian, 75 lire; English, 79 lire (Genoa); American, 78 lire (Genoa); demand continues very good. **Soda Crystals**, 50 lire. **Alum**, crystals, 85 lire; demand very fair. **Bicarbonate of Soda**, powder, bags, 159 lire (Genoa). **Bichromate of Soda**, 445 lire (Genoa); **Bichromate of Potash**, crystals, 590 lire. **Borax Crystals**, 99%, in kegs, 425 lire; in fair request. **Carbonate of Ammonia**, lump, 430 lire; powder, 370 lire; in brisk demand. **Carbonate of Magnesia**, pure, 430 lire; demand very fair. **Chlorate of Potash**, crystals, 290 lire; in little request; powder, 310 lire (Genoa). **Acetone**, pure, 98-99%, 1,250 lire; little called for. **Glacial Acetic Acid**, 99%, 1,300 lire. **Boric Acid**, crystals, 800 lire. **Lactic Acid**, 80%, 600 lire. **Bisulphite of Soda**, crystals, 350 lire. **Formaldehyde**, 40%, 860 lire. **Phosphate of Soda**, 160 lire; in better demand. **Hyposulphite of Soda**, crystals, 120 lire. **Metabisulphite of Potash**, 400 lire. **Nitrite of Soda**, 96-98%, dull at 295 lire. **Permanganate of Potash**, crystals, 800 lire; in little call. **Sulphate of Alumina**, crystals, 18%, 100 lire; 14-15%, 75 lire. **Sulphate of Zinc**, 180 lire. **Citric Acid**, crystals, 1,900 lire. **Sulphate of Iron**, 50 lire. **Hydrofluoric Acid**, 50%, 600 lire. **Oxalic Acid**, crystals, 660 lire. **Tartaric Acid**, crystals, 1,350 lire; a little better demand. **Chloride of Ammonia**, lump, 98-100%, 650 lire (Milan); powder, 95-96%, 325 lire (Genoa). **Chloride of Calcium**, 75-80%, 70 lire. **Bleaching Powder**, French, 110-115%, 90 lire; electrolytic, 100 lire. **Cream of Tartar**, 98-99%, powder, 930 lire. **Yellow Prussiate of Potash**, crystals, 2,000 lire. **Yellow Prussiate of Soda**, crystals, 1,400 lire. **Silicate of Soda**, Italian, 38-45%, 65 lire; crystals, 85 lire; English, 140° Tw., 100 lire; usual good demand. **Sulphate of Soda**, crystals, 43 lire; powder, 65 lire. **Sulphate of Magnesia**, crystals, 50 lire. **Chloride of Magnesia**, solid, 80 lire. **Hydrochloric Acid**, 20—21° Bé., 25 lire. **Sulphuric Acid**, 50Bé., 20 lire; 66 Bé., 45 lire. **Nitric Acid**, 36° Bé., 145 lire; 42° Bé., 180 lire. **Benzaldehyde**, 3,500 lire, in quiet demand. **Tannic Acid**, 80%, 2,000 lire; in fair request. **Aluminium Acetate**, 160 lire. **Lead Acetate**, yellow, 560 lire; white, 570 lire; in fair demand. **Beta Naphthol**, 2,800 lire; in fair demand. **Barium Peroxide**, 1,000 lire. **Sodium Peroxide**, 1,800 lire; in fair request. **Red Prussiate of Potash**, in fair inquiry, at 3,150 lire. **Caustic Potash**, 88-92%, 380 lire. **Tartar Emetic**, powder, 1,200 lire. **Mineral Superphosphate**, 28 lire. **Bone Superphosphate**, 52 lire. **Basic Slag**, 16-18%, 37 lire. **Nitrate of Soda**, 15-16%, 142 lire. **Nitrate of Ammonia**, 15—16%, 125 lire. **Nitrite of Lime**, 12—13%, 110 lire; in limited request. **Sulphate of Ammonia**, 20-21%, 170 lire; in good supply. **Sulphate of Copper**, 98-99%, Italian, 225 lire; foreign, 226 lire. **Chloride of Potash**, 72 lire. **Sulphate of Potash**, 90 lire. **Calcium Cyanamide**, 15—16%, 110 lire. **Sulphur**, refined, in blocks, 55 lire (Catania, Sicily); 70 lire (Milan). **Sulphur**, sublimed, 70 lire (Catania, Sicily); 77 lire (Genoa). **Green Olive Oil**, 360 lire; better requested. **Pure Olive Oil**, Riviera, 825 lire; Pari, 650 lire; Molfetta, 625 lire; Bitonto, 650 lire; Calabria, 625 lire; refined, 750 lire. **Crude Tar** fell from 325 to 320 lire.

LONDON METAL MARKET. Wednesday.

Copper: Standard brands, £64. 15s. to £64. 17s. 6d., cash; £65. 5s. to £65. 7s. 6d., three months; electrolytic, £71. 10s. to £72. **Tin**: Standard, £176. 2s. 6d. to £176. 5s., cash; £177. 5s. to £177. 7s. 6d., three months; Straits, £179.; English, £177. **Lead**, soft foreign, £23. 17s. 6d., prompt; English, £25. 5s.; chemical sheet, 33s. per cwt. for 2-ton lots, delivered. **Spelter**, prompt, £27. 15s.; hard, £25. 5s. **Antimony**, English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35. **Aluminium**, 98—99%, £115. to £120.; foreign, £110., c.i.f. **Nickel**, £130., delivered; £130. to £135. for export, f.o.b. **Mercury**, £10. 10s. **Bismuth**, 10s. **Platinum**, 500s. per oz. **Wolfram**, spot, 13s. per unit, c.i.f. United Kingdom or Continent. **Zinc Dust**, quotations are lower, as follows: Highest grade English, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET. Wednesday.

There has been rather better inquiry during the last week for heavy chemicals both on home and export account, but values generally continue in buyers' favour. For alkali products the home quotations are maintained at recent rates, though there are cheaper supplies offering from the Continent. **Bleaching Powder** unchanged at £11. 7s. 6d., softwoods, on rails. **Glauber's Salt** easier at £4. per ton, carriage paid, but only in small demand. **Chlorates** are in better request, **Potash** at 2⅞d., and **Soda** 2¾d. per lb. **Bichromates** are unchanged. **Roasted Saltcake** still in active request for export, and price firmer at £4. 15s. to £5. per ton, f.o.b. Liverpool; price for home consumption is unchanged at £4. 10s., carriage paid. Imported American **Sulphur** dearer at £5. 5s., on rails. For **Sulphate of Copper**

there is only small demand, and price nominal at £26. f.o.b. Liverpool. Quotations for **Phosphate** and **Commercial Hyposulphite of Soda** are easy, and business is reported as only small. **Nitrite of Soda** steady at £26. 10s., ex store. Concentrated **Sulphide** at £14. 10s. to £15. per ton, carriage paid. White powdered **Arsenic** is more plentiful, and price lower. Yellow **Prussiate of Potash** easier at 1s. 3d. per lb.; **Soda** unchanged at 7d., carriage paid. **Caustic** and **Carbonate of Potash** are freely offered, and prices have a lower tendency. Grey and brown **Acetate of Lime** continue in short supply, and price is well maintained. **Acetic Acid** firmer at £47. 10s., ex store, for 80%. **Acetate of Soda** in better request, and price firm at £24. 10s., ex store. **Miscible Wood Naphtha,** 6s. 9d. per gallon. **Acetone** quoted at £118. per ton. For **Lead Salts** there is more inquiry, and quotations are steady; white and brown **Acetate** £42., net, per ton, carriage paid. **Barium Chloride** easier at £14. 10s. to £15. per ton. **Green Copperas** is selling freely, but prices show no improvement. **Oxalic Acid** dull at 6d. to 6¼d. per lb., ex store. **Permanganate of Potash** lower at 9¾d. to 10d. per lb.

SWANSEA MARKET REPORT.

WEDNESDAY.

Very little business was transacted in **Tinplates,** the prices being on the basis of £1. 3s 1½d. per standard box, f.o.b. **Galvanised Sheets** met with a weak demand, and easier quotations £18. 7s. 6d. per ton, f.o.b. **Copper** exhibited weakness at £64. 12s. 6d. per ton prompt and £65. 2s. 6d. three months. **Tin** was neglected and easier at £176. 12s. 6d. per ton prompt, and £177. 17s. 6d. three months. **Lead** in small demand at £23. 17s. 6d. per ton for foreign prompt, and £23. 2s. 6d. three months; English, £25. 5s. **Spelter** depressed at £28. 2s. 6d. per ton prompt, and £28. 12s. 6d. forward. **Zinc Sheets,** £36. 7s. 6d. per ton f.o.r. **Sulphate of Ammonia** remains quiet for home wants at lower rates. **Sulphate of Copper** slow at £26. 7s. 6d. per ton, less 5% in casks f.o.b. **Nitrate of Soda** quiet, with prompt at £13. 7s. 6d. per ton, and forward £13. 12s. 6d. **Bone Meal,** little demand, with prompt at £8. 12s. 6d., in bags. **Sulphuric Acid** in steady demand at £3 12s. 6d. to £7. 2s. 6d. per ton on rails at works. **Pitch** firmer at £5. 12s. 6d. per ton, ex ship. **Oxalic Acid** remains in quiet demand at 6¼d. per lb. on rails. **Copperas,** in fair request at £2. 2s. 6d. per ton, including delivery certain radius. **Arsenic,** rather quiet, and down in price at £71. 2s. 6d. per ton for white powdered. **Turpentine** quiet, with American prompt at £4. 7s. 6d. per cwt. **Linseed Oil** steady, with raw prompt £2. 5s. 3d. per cwt. **Cottonseed Oil** firm, common edible £2. 3s. 6d., and deodorised £2. 6s. 8d. per cwt. **Cocoanut Oil** in fair demand and steady, with Ceylon at £2. 3s. 10d. per cwt. **Olive Oil,** quiet at £67. 7s. 6d. per ton. **Rape Oil** slow; refined, prompt, £2. 7s. 3d. per cwt. net in barrels. **Cod Oil** steady, with Newfoundland scarce and nominal. English, £1. 13s. 6d. per cwt. in barrels. **Palm Oil** very quiet; Lagos, prompt, £35. 10s. 6d.; soft, prompt, £36. 7s. 6d., and forward, £34. 15s. 3d.; mediums, £36. 10s. 6d.; and hards, £36. 15s. 6d. per ton. **Coal** steadier; best Admiralty smokeless, £1. 10s. to £1. 12s. 6d.; seconds, £1. 9s. to £1. 10s.; ordinaries, £1. to £1. 9s. Monmouthshire, black vein, £1. 9s. to £1. 10s., all per ton f.o.b. **Anthracite** firm, with supplies limited; best large, £2. 10s.; seconds, £2. 2s. 6d.; French nuts, £3. 2s. 6d. per ton f.o.b. **Patent Fuel** was rather quiet at £1. 15s. to £1. 17s. per ton f.o.b. **Cokes** on better supplies were offered more freely at £2. 10s. to £2. 12s. 6d. per ton f.o.b.; foundry, £2.; and furnace, £1. 10s. to £1. 12s. 6d., in trucks, at ovens.

LIVERPOOL CHEMICAL MARKET.

WEDNESDAY.

A steady but moderate demand for chemicals of the heavier kinds can again be reported as far as the home branch of the trade is concerned. Business in the textile branches of trade is reported to be quiet, but the few brighter and warmer days that have come have given a better tone to the market as presaging better trade. In the export branch of the trade there have been more inquiries for chemicals, and shipments have been fairly active. **Bleaching Powder** has had a freer inquiry and shipments have been on a fair scale. The price is £10. to £11. per ton for home-trade use and £11. per ton for export. **Calcium Chloride** has been rather more in demand, and is £5. 17s. 6d. per ton. **Caustic Soda** has had a very fair sale on home-trade account, and has been shipped freely for foreign ports. Quotations are: £20. 7s. 6d. to £21. 7s. 6d. per ton for 76 per cent., carriage paid, for the home trade, and £20. 10s. per ton for export. **Bicarbonate of Soda** has been rather more in demand for the home trade, and has had active shipments to overseas ports. It is £10. 10s. per ton, carriage paid, for use in the United Kingdom. **Soda Crystals** have been in fair demand on home-trade account, and are £5. 5s. per ton, carriage paid, for use in the U.K. **Nitrate of Soda** has again had a moderate inquiry, and is £13. 5s. to £13. 10s. per ton. **Borax** has been in very fair request. Commercial crystals are £27. per ton, and powdered, £28. Higher grades are: Crystals, £31. per ton; powdered, £32. per ton, carriage paid, in the United Kingdom. **Saltcake** has been more inquired for, on home-trade account, chiefly for forward dates. The price is £4. 10s. to £5. per ton for the home trade, and £5. 10s. to £6. per ton for export. **Bichromate of Soda** has been but little in request, and is 4½d. per lb. **Ammonia Alkali** has been steadily called for on home-trade account, and has again had a free shipment for foreign ports. It is £7. 12s. 6d. per ton for use by by the home-trade, and £8. per ton for export. **Hyposulphite of Soda** has been in fair request. It is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial, and £15. to £17. per ton, in 1cwt. kegs, for photographic. **Sulphide of Soda** has been very quiet. The price is £16. per ton for solid and £10. per ton for crystals. **Chlorate of Soda** has had a limited inquiry, and is 3d. to 3½d. per lb. **Phosphate of Soda** has moved but slowly, and is £15. to £16. per ton. **Prussiate of Soda** has been in moderate demand, and is 7d. to 8d. per lb. **Yellow Prussiate of Potash** has been quieter, and is 1s. 4d. to 1s. 4½d. per lb. **Red Prussiate** has had a limited sale, and is 4s. per lb. **Carbonate of Potash** has been but little called for, and is £26. to £32. per ton, according to quality. **Nitrate of Potash** has been rather more in request, and is £33. to £35. per ton for refined. **Chlorate of Potash** continues quiet, and is 4d. to 4½d. per lb. **Caustic Potash,** has been quieter, and is £32. to £33. per ton. **Permanganate of Potash** has been in good request, and is 10d. to 10½d. per lb. **Bichromate of Potash** has been inactive, and is 5¾d., c.i.f., to usual ports. **Salammoniac** has been rather more in request. First quality is £63. per ton; second quality is £60., and third, £57. **Sulphate of Ammonia** has had a very limited inquiry for use by the home-trade, but has had a rather active shipment for foreign ports. Neutral is £14. 15s. per ton, and ordinary £13. 12s. **Carbonate of Ammonia** has been steadily called for, and is 4d. per lb. **Muriate of Ammonia** has been but little in demand, and is £32. to £33. per ton. **Magnesia** has been rather more in request. **Carbonate** is £2. 5s. per cwt., and **Sulphate** £5. to £6. 10s. per ton. **Alum** has sold more readily. For the home trade £12. to £13. per ton is quoted, and for export £11. 10s. to £12. per ton. **Sulphate of Alumina** continues quiet, and is £8. to £12. per ton, according to quality. **Sulphur** has been more inquired for; flowers are £10. per ton, roll is £8. 10s., rock £8. to £8. 10s., and American £5. to £5. 10s. per ton. **Tartaric Acid** has had a moderate sale, and is 1s. 4d. to 1s. 4½d. per lb. **Cream of Tartar** has been in good request. It is £4. 10s. to £4 13s. per cwt. **Boric Acid** has been rather more in demand; commercial crystals are £50. per ton, and powdered £53., and £2. per ton more, if in casks. **Citric Acid** has been quieter, and is 1s. 9d. to 1s. 10d. per lb. **Oxalic Acid** has been inactive, and is 6¼d. to 6½d. per lb. **White Acetate of Lead** has been quiet, and is £43. to £44. per ton. **Sulphate of Copper** has been but little in demand, on home-trade account, but has been shipped more largely for foreign ports. It is £26. 10s. to £27. per ton, less 5 per cent., in casks, f.o.b. at Liverpool. **Arsenic** has had a very limited sale; white powdered is £71. per ton.

WEST OF SCOTLAND CHEMICALS.

WEDNESDAY.

The semi-stagnation experienced in this market lately contines to retard business, and trade during the week has been of small dimensions. There is little inquiry either on home or export account, and prices hold steady with the exception of white acetate of lead, which is 10s. lower, and magnesium chloride, which has been reduced to £3. per ton. Quotations at Glasgow, unless otherwise stated, are as follows. **Alum,** little doing, and in small demand; lump £13., and ground £12. 5s. per ton. **Arsenic** continues in short request, and supplies are still very scarce; it is quoted on spot at £77. net. **Barium Chloride** remains very quiet.

despite the recent reduction to £16. per ton. **Bleaching Powder** does not show much movement, and the quotation still stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax**, granulated is on offer at £26. 10s. per ton net, in 2cwt. bags. **Calcium Chloride**, 70—75 per cent. solid, £5. 12s. 6d. per ton **Citric Acid** remains a steady market at 1s. 8¾d. per lb., less 5%. **Copper Sulphate** is but little in request at last week's figure of £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar** firm, with better inquiry, and the price continues steady at £4. 10s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in quieter demand; brown steady at £40. 10s. per ton, net, and white lower at £40. 10s. per ton, net. The market for **Magnesium Chloride** is slower, with quotation reduced to £3. per ton. **Oxalic Acid**, at 6½d. per lb., is dull, but this price is still held. **Paraffin Wax** experiences a fair export trade at 2¾d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull round about 1s. 5d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1. 11s. per ton, but business is nominal. **Sodium Bichromate** remains steady, with business on the basis of 4¼d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2cwt. bags; and £11. 10s. in 1cwt. kegs. **Tartar Emetic**, 43—44%, in fair request at 1s. 1½d. **Tartaric Acid** still shows a quieter tendency at 1s. 3¾d. per lb.

AMMONIUM BICARBONATE—
Yokohama, 19 t. 19 c., £794.

AMMONIUM CARBONATE—
Adelaide, 5 c., £12.; Brussels, 1 t., £29.; Calcutta, 1 t. 14 c., £182.; Durban, 4 c., £9.; Hong Kong, 5 c., £17.; Kobe, 10 t., £308.; Melbourne, 2 t., £77.; Singapore, 1 t. 16 c., £124.

AMMONIUM CHLORIDE—
Bilbao, 14 cks., £175.

AMMONIUM NITRATE—
Harlingen, 241 cks., £1,396.
Kobe, 241 cks., £1,080.

AMMONIUM SULPHATE—
Antigua, 15 t., £227.; Canton, 50 t., £838.; Hong Kong, 350 t., £6,225.; Lisbon, 20 t., £310.

AMYL ACETATE—
Brussels, 1 drm., £54.
Melbourne, 3 drms., £177.
Pt. Elizabeth, 1 drm., £6.

ANTIMONY REGULUS—
Durban, 2 t., £56.

ANTIMONY SULPHIDE—
Bordeaux, 7 cks. £179.; Brussels, 6 cks., £42.; Buenos Ayres, 12 cks., £154.; Stockholm, 7 cks., £66.; Toronto, 2 cks., £26.

ANTIMONY TARTRATE—
Melbourne, 1 cs., £7.

ARSENIC—
Durban, 2 cs., £5.

BENZOIC ACID—
Sydney (F.), 2 kgs., £29.

BISMUTH—
Melbourne, 3 cs., £200.

BISMUTH CARBONATE—
Calcutta, 2 cs. (pt.), £5.
Brussels, 1 cs., £70.

BISMUTH SALICYLATE—
Brussels, 1 cs., £56.

BISMUTH SALTS (*otherwise undes.*)
Cochin, 33 cs. (pt.), £27.
Madras, 9 cs. (pt.), £5.

BISMUTH SUBCARBONATE—
Lyttleton, 5 pkgs. (pt.), £10.

BISMUTH SUBNITRATE—
Antwerp, 1 cs., £31.
Brussels, 2 cs., £118.
Sydney, 2 cs., £121.

BLEACHING LIQUOR—
Irish Free State, 2 brls., £16.

BONE FERTILISER—
Antwerp (F.), 50 t., £3,000.
Dunkirk, 7 t. 7 c., £121.

BONE FERTILISER—
Hamburg, 2 t. 10 c., £33.

BORAX—
Danzig, 3 t. 10 c., £77.; Durban, 1 t. (F.), £28.; Havana, 10 c., £15.; Pt. Sudan, 5 c., £27.

BORIC ACID—
Cochin, 1 c., £2.; Fremantle, 2 c., £10.; Jamaica, 2 c., £11.; Singapore, 1 c., £4.

CALCIUM ACETATE—
Irish Free State, 2 cks., £29.

CALCIUM CARBIDE—
Iddo, 6 cs., £6.

CAUSTIC POTASH—
Pt. Elizabeth (F.), 2 drms., £6.
Suva (F.), 2 c., £7.

CAUSTIC SODA—
Levuka, 2 c., £6.
Liban, 21 drms., £101.

Elizabeth, 1 cs. (pt.), £9.; Pt. Swettenham, 4 cs. (pt.), £27.; Sydney, 43 pkgs. (pt.), £23.; Valencia, 6 kgs., £38.

ETHER—
Bombay, 1 cs. (pt.), £9.
Haifa, 18 cs., £53.
Irish Free State, 2 pkgs., £12.

FERTILISERS (*otherwise undes.*)—
Channel Islands, 10 t. 9 c., £99.
Gothenburg, 1 t., £25.
Hamburg, 2 t., £29.

GALLIC ACID—
Calcutta, 2 cs. (pt.), £6.
Sydney, 1 cs., 1 kg., £71.

GLYCERINE—
Amsterdam, 1 c., £6.; Canton, 5 c., £28.; Cape Town, 1 c., £5.; Cape Town (crude), 5 t. 3 c., £240.; Havana, 1 c., £9.; Irish Free State, 4 c., £16.; Mollendo, 19 c., £96.; Philadelphia, 5 t. 2 c., £530

HYDROCHLORIC ACID—
Penang, 1 c., £5.

HYDROFLUORIC ACID—
Irish Free State, 1 bx., £16.

HYDROGEN PEROXIDE—
Accra, 2 cs., £12.
Irish Free State, 4 jars, £6.

HYDROQUINONE—
Melbourne, 2 cs., £43.

HYPOPHOSPHITE SALTS (*otherwise undescribed*)—
Perth, 3 cs., £37.

IODINE—
Calcutta, 2 cs. (pt.), £78.
Barbados, 1 cs., £7.
Rio de Janeiro, 1 cs. (pt.), £16.

IODINE (RESUBLIMED)—
Barcelona, 1 kg., £103.
Brussels, 6 cs. (pt.), £122.
Santander, 1 cs., £52.

IRON SULPHIDE—
Montreal, 2 cks., £5.

LEAD ACETATE—
Buenos Ayres, 1 ck., £6.
Delagoa Bay (F.), 40 kgs., £82.

LEAD NITRATE—
Beira, 1 kg., £8.

MAGNESIA—
Auckland, 10 cs., £24.; Bombay, 2 cs., £18.; Buenos Ayres, 3 cs., £23.; Gibraltar, 1 cs., £38.; Havana, 2 cs., £14.; Irish Free State, 70 bxs., £362.; Lyttleton, 10 cs., £24.; Mombasa, 1 cs. (pt.), £5.; Sydney, 10 cs., £24.; Wellington, 20 cs., £48.

MAGNESIA (CALCINED)—
Constantinople, 2 cks., £13.
Buenos Ayres, 1 cs. (pt.), £13.
Vera Cruz, 5 cs., £37.

MAGNESIUM CARBONATE—
Havana, 3 cs., £11.
Sydney, 43 pkgs. (pt.), £5.
Vancouver, 2 cs., £8.

MAGNESIUM CHLORIDE—
Dar-es-Salaam (F.), 8 drms., £17.

MAGNESIUM CITRATE—
Alexandria, 3 cs., £29.; Barcelona, 20 cs., £300.; B. Ayres, 2 cs. £16.; Calcutta, 14 cs., £141. Santander, 25 cs., £375.

MAGNESIUM SULPHATE—
Accra, 7 c., £15.; Brisbane, 1 t. 6 c., £31.; Buenos Ayres, 3 c., £6.; Canton, 5 c., £5.; Durban, 8 c., £10.; Fremantle, 1 t. 5 c., £34.; Ichang, 5 c., £7.; Irish Free State, 4 c., £17.; Melbourne, 1 t. 5 c., £30.; Melbourne, 4 t. 18 c., £118.; Singapore, 4 c., £12.; Sydney, 2 t. 10 c., £61.

MANGANESE BORATE—
Paris, 12 c., £57.

MERCURY BICHLORIDE—
Penang, 7 cs. (pt.), 1 kg., £30.

METHYL SALICYLATE—
Bombay (F.), 1 cs., £14.

MERCURY OXIDE—
Sydney, 1 cs., £25.

MERCURY SALTS (*otherwise undes.*)
Bilbao, 1 cs., £5.

METHYL ALCOHOL—
Bombay, 2 cs. (pt.), £10.

NICKEL SALTS (*otherwise undes.*)—
Melbourne, 3 cs., £7.

NICOTINE SULPHATE—
Copenhagen, 1 drm., £32.

NITRIC ACID—
Alexandria, 1 c., £5.
Wellington, 1 c., £26.

OXALIC ACID—
Calcutta, 2 cs., £9.

PHOSPHO CITRIC ACID—
Delagoa Bay, 5 cs., £28.

PHOSPHORIC ACID—
Penang, 1 cs., £5.
Pt. Elizabeth, 1 cs., £6.
Sydney, 59 cs., £173.

POTASH (PEARL ASH)—
Dunedin (F.), 2 cks., £28.

POTASSIUM BICHROMATE—
Buenos Ayres, 1 ck., £7.

POTASSIUM CITRATE—
Auckland, 1 cs., £8.
Brisbane, 1 cs., £15.
Sydney, 3 cs., £39.

POTASSIUM IODIDE—
Bangkok, 2 cs., £185.; Bilbao, 1 cs. (pt.), £44.; Brussels, 8 cs. (pt.), £332.; Calcutta, 1 cs., £88.; Christiania, 1 cs. (pt.), £63.; Cochin, 33 cs. (pt.), £28.; Durban, 2 cs. POTASSIUM PERMANGANATE—
Melbourne, 7 pkgs. (pt.), £23.
Pt. Elizabeth (F.), 3 cs., £14.

POTASSIUM PRUSSIATE—
Hamburg, 10 cks., £290.
Irish Free State (F.), 1 ck., £47.
Shanghai, 1 ck., £16.

POTASSIUM SALTS (*otherwise undescribed*)—
Cochin, 33 cs. (pt.), £8.

POTASSIUM SILICATE—
Bilbao, 20 drms., £35.

POTASSIUM SULPHATE—
Callao, 1 cs., £32.

SALAMMONIAC—
Beira, 2 c., £7.; Havana, 2 c., £5.; Hong Kong, 3 c., £14.; Kilindini, 1 t. £38.; Pt. Elizabeth 2 c., £6.; Singapore, 1 c., £5.

SALICYLATES (*otherwise undes.*)—
Montreal, 1 cs. (pt.), £12.
Sydney, 4 cs. (pt.), £89.

SALICYLIC ACID—
Bombay, 3 cs. (pt.), £6.; Cape Town, 1 cs., £6.; Durban, 1 cs., £8.; Calcutta, 1 cs., £7.; Jamaica, 1 cs. (pt.), £6.; Melbourne, 2 cs., £24.

SALTPETRE—
Beira (F.), 5 c., £9.; Canary Islands (F.), 9 t. 18 c., £280.; Irish Free State, 1 t., £45.; Pernambuco, 1 t., £41.; Pt. Elizabeth, 13 c., £29.; Rio de Jan., 1 t., £39.; Sydney, 3 t. 1 c., £125.; Wellington, 2 t., £78.

SILVER NITRATE—
Bombay, 3 cs. (pt.), £7.
Calcutta, 2 cs. (pt.), £11.
Shanghai, 1 cs., £110.

SPENT OXIDE—
Hamburg, 601 t., £908.

SODA ASH—
Malta, 6 c., £5.
Rotterdam, 6 c., £5.

SODA CRYSTALS—
Shanghai, 1 t. 16 c., £14.

SODIUM ACID PHOSPHATE—
Melbourne, 100 kgs., £400.
Sydney, 60 pkgs., £240.
Toronto, 25 cs., £100.

SODIUM ACID PYROPHOSPHATE
Delagoa Bay, 10 kgs., £35.

SODIUM BICARBONATE—
Bilbao, 2 c., £6.; Durban, 9 c., £14.; Irish Free State, 5 c., £11.; Lourenco Marques, 5 c., £8.; Monte Video, 2 c., £9.; Sydney, 10 c., £20.; Valencia, 10 c., £24.

SODIUM BISULPHITE—
Buenos Ayres, 10 t., £190.
Penang, 1 t. 10 c., £31.

SODIUM HYPOSULPHITE—
Colombo, 11 c., £10.

SODIUM IODIDE—
Bilbao, 1 cs., £49.
Christiania, 1 cs. (pt.), £24.
Sydney, 1 cs. (pt.), £7.

SODIUM METABISULPHITE—
Valencia, 1 t., £20.

SODIUM PRUSSIATE—
Hamburg, 5 brls., £32.

SODIUM PYROPHOSPHATE—
Melbourne, 1 t. 3 c., £51.

SODIUM SALICYLATE—
Pt. Elizabeth, 2 pkgs., £27.

SODIUM SULPHATE—
Barnados, 2 t. 10 c., £16.
Callao, 1 cs., £32.
Irish F. State, 2 t. 6 c., 2 cks., £46.

SODIUM SULPHITE—
Bushire, 1 t., £40.
Penang, 5 c., £7.
Sydney, 20 drms., £50.

SODIUM SULPHITE (ANHYDROUS)—
Rotterdam 1 t. 3 c., £12.

SODIUM TARTRATE—
Sydney, 1 t., £73.

SULPHURIC ACID—
Alexandria, 3 c., £23.; Bombay, 2 c., £10.; Calcutta, 1 c., £5.; Iddo, 4 c., £10.; Colombo 1 c., £20.; Pt. Elizabeth, 5 c., £16.; Santos, 7 c., £20.

SUPERPHOSPHATE—
Hong Kong, 6 t., £49.

TANNIC ACID—
Melbourne (F.), 1 cs. (pt.), £19.

TARTARIC ACID—
Bucharest, 2 c., £17.; Calcutta, 5 c. (F.), £32.; Canton, 1 c., £5.; Colombo, 1 c., £8.; Danzig, 5 t., £687.; Durban, 7 c., £52.; Pt. Elizabeth, 3 c., £22.; Rangoon, 1 c., £11.

THEOBROMINE—
Bilbao, 1 cs., £11.

TIN OXIDE—
Brussels, 3 cks., £81.

TITANIUM POTASSIUM OXALATE
Auckland (F.), 2 kgs., £26.

ZINC AND MAGNESIUM FLUOSILICATE—
Paris (F.), 1 brl., £50.

ZINC CHROMATE—
Melbourne, 1 ck., £25.

ZINC OXIDE—
Boulogne, 2 cks., £12.; Copenhagen, 160 cks., £567.; Durban, 5 cks., £13.; Paris, 100 cks., £440.; Petrograd, 59 brls., £150.; Sydney, 2 cs., £12.

ZINC SULPHIDE—
New York, 2 cks., £98.

Week ending June 30.

ALBUMEN—
Amsterdam, £325.

BEESWAX—
Auckland, 1 t. 3 c.
Rotterdam, 1 t.

CARNAUBA WAX—
Genoa, 10 c.

FULLER'S EARTH—
Dunkirk, 5 t.; New York, 20 t.; Ostend, 1 t.; Philadelphia, 25 t.

GLUE, SIZE, AND GELATINE—
Bombay, 1 c.; Brussels, 2 c.; Calcutta, 4 t.; Colombo, 12 c.; Jamaica, 3 c.; Karachi, 10 c.; Kobe, 5 t.; Melbourne, 1 t. 1 c.; New York, 2 t. 3 c.; Perth, 2 c.; Pt. Elizabeth, 11 c.; Riga, 1 t. 10 c.; Shanghai, 12 t. 11 c.; Sydney, 2 t. 1 c.; Vancouver, 3 t. 5 c.; Wellington, 19 c.

LEAD ASHES—
Antwerp, 6 t. 3 c.

MINERAL WAX—
Brussels, 6 t.

PARAFFIN WAX—
Ghent, 10 c.; Genoa, 2 t. 9 c.; Haifa, 1 c.

PLUMBAGO—
Antwerp, 1 t. 1 c.
Gothenburg, 10 c.

QUININE—
Bombay, £6,036.; Calcutta, £8,548.; Colombo, £5,920.; Durban, £20.; Constantinople, £2,105.; Rio de Janeiro, £501.

ROSIN—
Ghent, 8 c.

SALT—
Delagoa Bay, 7 c.; Fiji Islands, 61 t. 13 c.; Funchal, 1 c.; Lourenco Marques, 2 c.; Madras, 14 c.; Pt. Said, 3 c.; Saigon, 8 c.; Tanga, 3 c.

SHELLAC—
Danzig, 2 c.

SOAP—

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers)	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."
Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.
Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

PRE-WAR AND POST-WAR DYESTUFFS PRICES.

THE actual position of the British Dyestuffs Corporation, as disclosed by the report and accounts for the year ended October 31, 1922, and by the chairman's speech at the annual general meeting, is not easy to summarise. Although a trading profit of £102,000 is claimed for the year, yet when the unknown amount estimated to be recoverable in respect of E.P.D. and the sums obtained by the liquidation of surplus stocks are taken into account, the trading profit is seen to be more apparent than real. The most optimistic shareholder, however, could hardly have expected a dividend on the year's working, and the general tone of the meeting showed complete satisfaction with the chairman's explanations and encouraging presentation of the facts. In view of the attitude of the Colour Users' Association, the question of the prices at which dyestuffs could be sold by the Corporation came in for detailed review. The colour users have expressed their well-considered opinion that a margin of 200 per cent. over pre-war prices for all dyestuffs should leave an adequate amount of profit to the makers, but Sir William Alexander strongly combatted this view. He pointed out that on the average the selling price of dyestuffs had been reduced from 3s. 5d. per pound in 1921 to 2s. 6d. per pound in 1922, and that in many cases the maximum price limits stipulated by the Colour Users' Association were not exceeded. In many other cases, however, it would be quite impossible to produce colours and sell them at a reasonable profit at three times their pre-war price. Sir William estimated that actual working costs had increased by 170 per cent. over pre-war, and that if the colour users' suggestions were rigidly adhered to, the amount of profit available for development and reserve would be infinitesimal. In arriving at his figure of 170 per cent. the chairman stressed a point which we ourselves have raised on previous occasions, namely, that direct comparison between the pre-war German dyestuffs industry and our own post-war industry is vitiated unless one very important factor is taken into consideration. After all, the world's dyestuff consumption capacity is limited, and whilst Germany prior to 1914 had practically the whole of the world's markets at her disposal, and was enabled thereby to keep her plants running continuously at full capacity, none of the huge dye-making establishments that have been set up in America, France, Italy, or this

country will ever be in this fortunate position. Continuous operation of plant does not only mean lessened overhead charges, including lower depreciation losses, but it is only by continuous operation over a long period of time that both chemists and workmen can acquire that intimate familiarity with the details of plant operation which alone can lead to maximum efficiency. Sir William Alexander estimated the figure of 35 per cent. as the permanent addition to pre-war production costs due to intermittent plant operation, and this is a factor which, so long as international competition in dyestuffs manufacture exists, is bound to persist. The whole position is decidedly difficult. Germany, if presented with the opportunity of unrestricted world trade, and aided by the ridiculous international value of the mark, could certainly undersell and eliminate all her competitors in the dyestuffs industry. Prices of colours would be very low until it served her purpose to raise them, as she undoubtedly would do after all competition had been removed. Even at normal rates of exchange Germany's forty years' experience of intensive manufacture would suffice to enable her to regain her world supremacy in the dyestuffs' trade. But so long as conditions of national security compel the great powers of the world to establish huge dyestuffs factories of their own, each with a capacity very nearly equal to supplying the whole of the world's demands, just so long must prices remain considerably higher than would be the case were the world's production concentrated in one huge combine. This state of affairs, which seems peculiar to the organic chemical manufacturing industry, must not, in fairness to British producers, be lost sight of. The establishment of the British industry demands sacrifice, and the problem is to see that this sacrifice is spread equitably over the colour user, the shareholder, and the tax-payer. Reverting to the affairs of the Corporation, the general conclusion would seem to be that during 1922 the work of consolidation was steadily advanced, the internal friction reduced to a minimum, and the utmost economy effected without prejudice to efficiency. Criticism of the directorate on the grounds of its non-technical personnel was again heard at the meeting. Only the future will prove whether such criticism is justified or not. After all, the information vouchsafed to shareholders at annual general meetings is very limited. Every care must be taken that no important information is allowed to become available to competitors, and shareholders must in most cases accept on trust the generalised statements of the chairman. Sir William Alexander again intimated that the present Board was but temporary, and that when the affairs of the Corporation assumed a sound financial aspect the ranks of the directorate would be recruited from the generation of experienced technical men now growing up in the services of the Corporation, an intimation which augurs well for the future.

THE NEW GERMAN MINERAL OIL COMBINE.

The reports in the German Press to the effect that Hugo Stinnes intends still further to increase his manifold activities by the creation of a vertical trust controlling practically the whole of the German liquid-fuel industry, is of more than ordinary interest to the chemical industry. Two of the four great combines, the activities of which Stinnes contemplates co-ordinating, are the holders of the patent rights of processes which are the most important contributions to liquid-fuel technology that Germany has made within recent years. We refer to the Olea Mineralwerke Aktiengesellschaft, which controls the Melamid patents for the production of light oils by the cracking of crude petroleum, and to the Aktiengesellschaft für Petroleum Industrie, which possesses the sole rights of the Bergius process for the direct hydrogenation of coals and heavy tars. So far as can be deduced from the absence of published results, neither of these two processes has evolved much beyond the experimental stage, but it is known that their inventors and financial backers are confident of ultimate success.

PEAT PRODUCTION AND UTILISATION.

A report on the progress of the peat industry in America during the year 1922 has just been issued by the United States Geological Survey. When compared with the previous year, considerable progress is to be reported, the weight of peat produced in 1922 being 100 per cent. above the 1921 figure, and the increase in value being 52 per cent. As a fertiliser itself, or in the production of mixed fertilisers, the use of peat increased 96 per cent. in quantity, and there has also been a decided growth in its employment as an ingredient in cattle feeding-stuffs. Further, the use of peat as a fuel developed considerably, although this, we should think, has been due to the shortage of coal in the winter of 1922. The total consumption of peat and peat moss was 64,074 tons during the year, valued at 421,000 dollars, and this figure includes some imports. It should be noted, however, that although the figures for 1922 are a considerable improvement on 1921, they do not show any very great increase in production during the last ten years, the record output, for example, being in the year 1918, when the figure was over 100,000 tons. We must confess, though, that the general prospects for the extended utilisation of peat, except in a small way as an ingredient of fertilisers, do not seem to be very bright. There is nothing new in the direction of improved methods to report from America which would tend to alter this opinion. Our own Fuel Research Board is still actively investigating the possibilities of Irish peat, and has appointed Professor Pierce Purcell as peat investigation officer. Air-drying is apparently the only method by which the water-content of the peat can be reduced economically to the point at which the material can be employed as a fuel, and the Fuel Research Board have just published a voluminous report on this subject. The large areas over which the peat must be worked, and the necessity for spreading the material on the ground in thin layers for the purpose of drying, make the problem almost entirely an engineering one, the immediate prospects for the solution of which are not too encouraging.

THE TECHNOLOGY OF ABRASIVES.

NATURAL AND ARTIFICIAL PRODUCTS.

By "INVESTIGATOR."

UNTIL about thirty years ago natural abrasives only were in use, the chief of these being sandstone, emery, corundum, garnet, and the diamond. Since 1890, however, the availability of cheap electrical energy, together with the development of the industrial electric furnace, have led to the establishment of the artificial abrasive industries at Niagara Falls and in the Hautes Pyrénées (Southern France). The principal manufactured abrasives are carborundum, alundum, and corubin, the host of others being substantially the same materials under various trade names.

In the year 1918 the total value of all the abrasives consumed in the United States was close on 11 million dollars, manufactured products accounting for 74 per cent. of this figure, which does not include quartz and felspar. In the same year upwards of 5 million dollars' worth of abrasive products were exported from America, whilst the value of the imports exceeded one million dollars. For 1918 the Canadian production of artificial abrasives was upwards of 70,000 short tons, the U.S.A. producing 58,000 short tons in 1917 (value 8,137,242 dols.). These figures will serve to emphasise the magnitude of the industries.

Natural Abrasives.

Abrasives appear to conform to the rule that hardness and complexity of composition are inversely related, so that the diamond, as an element, stands first with hardness 10 on Moh's scale. Black diamonds ("carbonado") and inferior colourless material ("boart") are used for rock-drills and diamond-cutting respectively. Sandstones consist largely of quartz particles (hardness 7) cemented together by silica, those used in the cut-glass industry being almost pure quartz. The colour of black sandstones is due to manganese dioxide. Compact varieties of quartz such as hornstone are made into oilstones and whetstones. Non-crystalline varieties of silicia, such as tripoli and infusorial earth, are used in the form of compressed tallow cakes for "cutting down," as a preliminary to polishing, while abrasive bricks may be made by baking a mortar composed of infusorial earth (88 per cent.), lime (10 per cent.), aluminium and sodium sulphates 1 per cent. each), (*Brit. Pat.* 129,505 of 1918). Flint is used for making "sand" paper and the "flint-blocks" used for lining tube-mills.

Emery, Corundum, and Garnet.

Emery (hardness 9), the "naxium" of the ancients, consists of alumina, together with magnetite and hematite. It occurs as loose surface masses in the Greek Island of Naxos, where very primitive mining methods are in vogue, masses too large for transport being disintegrated by alternately heating and quenching. At Chester, Mass., the deposits are much less accessible, and extensive tunnelling is necessary. Spinel emery, $MgAl_2O_4$ (hardness 8) is found at Peekshill, in New York State. The density lies between 3.7 and 4.3, with Al_2O_3 content from 30 to 70 per cent. The abrasive power or effective hardness is not rigidly parallel with the Al_2O_3 content, but is affected by the nature of the impurities and the structure. Before grading, the material is examined under the microscope, especially for the presence of mica, which is very deleterious in making vitrified or pottery wheels. Owing to the presence of iron oxide, emery gives a good finish in use, and in the manufacture of cloth, etc., presents a better holding surface for the adhesive than carborundum, because of its rougher fracture.

Corundum (hardness 9, density 3.9—4.1), consists of alumina with traces of silica, iron oxide and water, and is mined in Ontario. The crushed mineral is concentrated by flotation, dried, and after passing over magnetic separators, is screened into twenty sizes (1/8 to 1/200 inch). The sieved material is subjected to a current of air which blows away any silica. Before grading, it is examined by the naked eye for pyrites and hornblende, by the magnet for magnetite, and analysed chemically for alumina and iron content. Corundum is a faster cutting abrasive than emery.

Garnet (hardness 6.5—7.5), comprises a variety of double calcium and aluminium silicates, and is utilised as a wood abrasive in the form of paper or cloth. The so-called "Spanish mineral," which is largely used, is probably an iron aluminium garnet, $Fe_3Al_2Si_3O_{12}$, and is prepared for use by methods similar to those employed for corundum.

Artificial Abrasives.—Carborundum.

The first artificial abrasive, second only to the diamond in hardness (9.5 on Moh's scale), was obtained by E. G. Acheson in 1891, while attempting to crystallise carbon from a bath of molten aluminium silicate. At first it was thought to be a compound of carbon and corundum, hence the name, but analysis showed it to be silicon carbide, SiC.

Petroleum coke and pure white sand (99.5 per cent SiO_2) are the usual raw materials, but charcoal, anthracite, pitch coke and furnace coke (10 per cent. ash) can also be employed. Lampblack, however, cannot be used, so that the suitability for the purpose under consideration is not a question of purity, but seems to be connected with the readiness with which the varieties of carbonaceous material change to graphite on heating. Sawdust and salt are added, the former to maintain porosity, and so to facilitate the escape of the large volumes of carbon monoxide generated, the latter to act as a flux for the impurities until it is volatilised. A typical charge would consist of 1,500lb. petroleum coke, 2,520lb. white sand, 300lb. sawdust, and 40lb. of salt, much of which serves to insulate the central reacting mass, and is recovered. The most recent type of furnace is 30ft. long by 12ft. wide, with a production of 15,000lb. of carborundum per run. A current of 6,000amps. is maintained, the voltage being gradually decreased from 190 to 125 at the end of the run of 36 hours. After cooling 24 hours, the crystalline mass is crushed in high-speed mills provided with 2-ton manganese-steel rolls, treated with sulphuric acid (1:2) for three days at 100° C. in lead-lined vats to remove surface impurities, washed, dried in rotary dryers, and finally screened to sizes from 1/6 to 1/220 inch. After washing the crystals contain 69.1 per cent silicon and 30.2 per cent carbon. The crushing rolls need renewal every six months, while the fine silk screens wear readily, necessitating constant checking of the finer grades. Very fine grades known as "flours" (F, FF, and FFF) are made from the crushed material by levigation methods. Graphite and much amorphous carbide result, the latter by-product ("carbofrax" and "refrax"), being extensively utilised as a refractory and for zinc distillation retorts. In 1918 the production cost per short ton (2,000lb.) amounted to 195 dols., of which 24 dols. was for power.

Carbosolite, a German silicon carbide of a dark grey colour, has been much used for granite finishing, while carbolon, crystolon, electrolon, samite and exolon are trade names of other American and Canadian carborundum products.

Owing to the centrifugal forces developed at high speeds, abrasive wheels work under considerable strain, so that the lighter the abrasive the safer the wheel. In this respect, carborundum, with density 3.2, compares very favourably with denser abrasives. When made from exceedingly pure materials, it is colourless, but as ordinarily produced, the crystals may be black, green, pale-blue or purple. Although harder than corundum, it is more brittle, and breaks down to powder much more rapidly. It has largely replaced corundum for grinding brittle materials such as cast-iron, marble, mother-of-pearl, etc., and for finishing leather. Owing to its low tensile strength and to the fact that its fracture is crystalline and not conchoidal, it is not suitable for steel grinding, the constantly freshly exposed edges tearing into the tough steel surface. As it tends to clog up, carborundum paper is less suitable than flint or garnet paper as a wood abrasive. It is three or four times as fast as emery, in use, but in common with the other artificial products, it is not suitable for glass polishing.

Artificial Alumina Abrasives.

Artificial corundum has been known for nearly a century, from the time true rubies were first made. Hasslacher, in 1894, prepared corundum free from iron by heating crushed emery ore with charcoal or coke in the electric furnace. The commercial material, alundum, is now manufactured from bauxite, by fusing with coke and iron borings for 24 hours in a water-cooled steel electric furnace, a charge consisting of 1,750lb. calcined bauxite, 100lb. coke, and 350lb. iron borings (*J. Amer. Electrochem. Soc.*, 1917). The oxide impurities are reduced and settle to the bottom, together with ferro-silicon, the fused alumina being obtained as a large ingot on taking down the furnace. It is claimed that by regulating the rate of cooling and by stirring the molten mass, an "abrasive temper" can be imparted, analogous to the temper of steel.

Aloxite is an artificial corundum made from bauxite in the Hautes Pyrénées, near supplies of raw materials and

hydro-electric power. Corindite is made from red bauxite by smelting with anthracite and blowing air through. It is a spongy mass containing many fine crystals of alumina (*French Pat.* 471,513 of 1915). Borocarbone is a French aluminous abrasive stated to be capable of being "tempered." Oxalumina consists of small crystals of alumina, while the product of fusing alumina with silicon constitutes another abrasive (*French Pat.* 430,932 of 1911).

The toughness of an alumina abrasive is increased by adding small amounts of oxides such as silica, iron oxide, titanium dioxide, strontia and zirconia. A high-grade product would consist of 97.4 per cent. Al_2O_3, TiO_2 1.38 per cent, Fe_2O_3 0.32 per cent., and SiO_2 0.90 per cent. The abrasive power may be weakened by imparting a cellular structure to the "grain." For this purpose the alumina is fused with a volatile sodium compound (*U.S. Pat.* 1,263,709 of 1918). Unlike carborundum, alundum can be used with good results for grinding hardened steels and malleable iron, the particles becoming polished in use. It is less brittle than natural corundum, and is much more reliable on account of its uniformity. The cost of production in 1918 was 90.5 dols. per short ton, the power cost being 7.8 dols. This comparatively low energy expenditure would render the manufacture feasible in this country.

Miscellaneous Artificial Abrasives.

A product having abrasive properties results when a mixture of aluminium with metallic oxides or peroxides is ignited. Corubin, the slag produced in the manufacture of chromium by the Thermit process forms an excellent abrasive. It contains 72 per cent. of alumina and 13 per cent. of chromium, and is used for lens grinding. Other metallic slags obtained by this process have been utilised.

"Diamond-crushed steel" made by quenching white-hot crucible steel and crushed cast iron are abrasive powders used for cutting granite, marble, and glass. "Angular grit" (crushed chilled iron) is a similar product which has found application as a substitute for sand in sand-blasting, the tendency to form dust being much less pronounced. Ferro-chromium containing about 30 per cent. chromium, together with up to 3 per cent. of silica, has also been patented. Tantalum metal and Moissan's boride and silicide of carbon, CB_6 and SiB_3, may also be of service in this field.

Analytical Methods.

Artificial corundum can be differentiated from the natural product under the microscope, the former containing microscopic bubbles of gas. The presence of carborundum in quantities not less than 5 per cent. can be detected by heating the sample, after ignition, with lead chromate (20 parts) in a tube of hard glass, when the mass becomes red-hot. For abrasives containing a small proportion of carborundum, the material, after ignition, is oxidised with lead chromate and potassium chlorate for one hour in a current of CO_2-free air. The gases after washing with silver-nitrate and ferrous-sulphate solutions, are passed into baryta water and the CO_2 estimated. Another method is to treat the residue insoluble in fused potassium bisulphate with hydrofluoric and sulphuric acids, until a constant weight is obtained.

THE PICKLING PROCESS IN TINPLATE MANUFACTURE.*

THE MECHANISM AND EFFICIENCY OF "RESTRAINERS."

During the process of manufacture of mild-steel plates for treatment in the tinning bath in the production of finished tinplates the surface of the metal becomes coated with oxide-scale, the removal of which is the function of the pickling process. Two varieties of oxide scale are recognised in the trade. The first is a heavy blue-black coating, formed during the production of the plates from steel bars rolled down hot in the mills; the second a thinner layer or scale, formed during annealing processes at a later finishing stage. Oxide-scale or iron-scale, as it is sometimes called, is a compound of ferrous and ferric oxides in varying proportions. The inner layers are not magnetic, and approximate in composition to $6FeO,Fe_2O_3$; the outer layers of the scale are magnetic and are nearer in composition to ferro-ferric oxide FeO,Fe_2O_3 (Fe_3O_4).

It is the object of the pickling process to effect the removal of this scale, as tin will only adhere to a clean metal surface. To remove the scale the plates are immersed in warm dilute sulphuric acid. The heavy blue-black scale is removed by what is known as the "Black Pickling" Process, the lighter scale by the "White Pickling" Process. Both processes are similar in character, save that, in the latter, conditions are made less severe in respect of strength of acid, temperature of bath, and time of contact of the plates with acid. It has been usually supposed that the loosening of the scale is effected by hydrogen produced below the surface of the scale and at the expense of the metal—in other words, that the scale is "burst off" by the evolved gas—and in practice a quiescent bath is an object of suspicion to the "pickler," who likes to see a good seething boil from the plates and has fresh acid and steam at hand to liven up his bath if the process appears sluggish.

The Addition of "Sharps" to the Bath.

From an early date it has been the practice at certain works to reduce the consumption of acid in the pickling process by addition of "sharps" to the acid bath. At a later date proprietary articles were employed on a limited scale for the same purpose, and the fact was established that conditions could be set up in the pickling bath, which reduced the evolution of hydrogen without appreciably increasing the time necessary for complete removal of the scale. This controlling effect of what may be termed "restrainers" remained obscure, and no attempt appears to have been made to elucidate the rationale of the process by detailed research, either in the works or in the laboratory. The conditions at the pickling bath, *qua* evolution of acid fume, have long been a matter of concern to the inspector, quite apart from loss of acid in the process and injury to the surface of the plates caused by excessive action of acid on the metal, and it appeared desirable that research should be undertaken in the laboratory of the chief inspector at Cornwall House, with a view to deciding whether the escape of noxious and offensive gases at the pickling bath could not be lessened without undue interference with the process of manufacture. The scope of the work had necessarily to be limited to a determination of the factors that control the pickling process with or without the addition of restrainers, and under the simplest laboratory conditions, but the results obtained encouraged the belief that a more scientific control of the pickling process would effect notable economies, and it was thought well to place manufacturers at once in possession of the salient facts rather than delay progress by waiting for the publication of the Alkali Report. To this work of elucidation and inquiry Mr. H. J. Bailey has made notable contributions, and, indeed, it is in great measure owing to his industry and perspicacity that the difficulties inherent in the translation of laboratory into large-scale practice have been successfully surmounted, and that the improved process is now in successful operation at so many of the South Wales works.

The Scale Dissolved, not Burst Off.

Test shows that ferric iron is absent from the solution and that ferrous iron alone is present. Further test shows that when a strip of metal freed from scale by preliminary treatment with acid, is employed, the volume of hydrogen gas evolved is equivalent to the loss of weight of metal. Solution of the scale must therefore have been effected by reduction of the ferric oxide contained therein to ferrous oxide. These considerations led to the hypothesis that the pickling process proceeds normally on the lines of the following equations:—

I. (*a*) $Fe + H_2SO_4 = H_2 + FeSO_4$.

(*b*) $FeO,Fe_2O_3 + H_2 + 3H_2SO_4 = 3FeSO_4 + 4H_2O$.

Summarised as—

$$FeO,Fe_2O_3 + Fe + 4H_2SO_4 = 4FeSO_4 + 4H_2O.$$

II. $Fe + H_2SO_4 = FeSO_4 + H_2$.

Reaction II. accounts for the hydrogen gas evolved, and 1 gramme of iron is here equivalent to 400 c.c. of hydrogen (0° C. 760 m.m.).

This fact, combined with the results of a large number of experiments, have led to the conclusion that the scale is *dissolved*, therefore, not *burst off*, as formerly supposed.

Measurement of Hydrogen Evolved.

If a small strip of mild-steel plate, containing oxide scale on its surface, be immersed in warm dilute sulphuric acid

* From the detailed account of investigations conducted by the Alkali Inspectorate given in the Annual Report for 1922. London: H.M. Stationery Office, 1s. 6d. net.

(say, 5 per cent. strength) the scale is dissolved and hydrogen gas is evolved, which may be collected and measured. The rate of evolution of gas increases as the metal dissolves and at higher temperatures becomes tempestuous in the course of 60 to 70 minutes. When a small amount of size, say 0.1 per cent. of size (glue), is added to the acid bath, solution of scale proceeds as before, but the volume of hydrogen evolved is greatly reduced and the rate of evolution remains practically constant. When acid alone is used, the surface of the metal plate is left pitted and rough; with size added, on the other hand, the surface remains smooth. Thus, with a strip of mild steel, 10.9 grammes in weight and of a total area 3,000 sq. mm., the following results were obtained:—

Volume of Hydrogen Evolved, 0° C., 760 mm. 60° C.

Period.	A. Size present.	B. 400 c.c. of Acid only (5.3 per cent. H_2SO_4).
First 15 mins....	3.5	11.5
Second ,, ...	3.5	31.5
Third ,, ...	3.0	44.5
Fourth ,, ...	4.5	61.5
Fifth ,, ...	4.0	69.0
Sixth ,, ...	4.5	72.0
Seventh ,, ...	4.5	78.0
Eighth ,, ...	5.5	82.0
Total Hydrogen.	33.0 (=0.082g. Fe).	450.0 (=1.120g. Fe).
Total loss of weight of metal plate	0.500 gramme.	1.450 gramme.

"Restrainers" and Protective Coating of Hydrogen.

Attention has already been drawn to the effect of traces of size (0.1 per cent.) in restricting the action of acid on clean metal in the pickling process. This property of rendering the iron "passive" or "polarised," so to speak, is one possessed, though in differing degree, by many organic substances, such as dextrin, glucose, gelatine, starch substitutes, and other proprietary articles. In every case the rate of evolution of hydrogen is reduced at all temperatures, while the rate of solution of the scale itself is but little affected. This differential effect is of great importance in the pickling process, as it is essential that complete removal of the scale should be effected with minimum time of contact of the metal with acid. It has been suggested that the specific action noted is due to a modification of the ionisation conditions in the bath; but experiment shows that the effect of the limited amount of restrainer added is minimal under the conditions of the test, and in any case the hypothesis affords no explanation of the fact that the *clean* metal surface alone is rendered "passive," the scale remaining unaffected. A simpler explanation is one based on the fact that the hydrogen gas evolved in Equation I. (*a*) is all consumed in the reduction of ferric to ferrous oxide, while in Equation II. the evolved hydrogen is free to escape from the solution. It appears probable, therefore, that in presence of a restrainer the bubbles of hydrogen are stabilised on the surface of the metal (*cf.* froth flotation process) thus forming a protective coating, which comes into being automatically as the scale is removed, and retards further action of acid on the metal. The correctness of this hypothesis is supported by the facts revealed by an examination of the metal surface under the microscope. If a small strip of clean metal plate, or better a piece of iron wire of fine gauge, be immersed in a drop of size-acid solution placed on a glass slide under a one-inch objective, the surface of the metal is seen to be covered with a "moss" of minute bubbles, that show little or no tendency to enlarge and escape from the solution; while, if acid alone be used, the bubbles enlarge and break away.

Experimental Results and Conclusions.

Comparison was made of the "Efficiency" of various restrainers under controlled conditions. The apparatus employed was of the simplest description and included a large water bath, two Erlenmeyer flasks (capacity about 415 c.c.), each provided with rubber stopper and small-bore tube delivering to an inverted graduated cylinder standing in a pneumatic trough. For the experiments with size (jelly), cylinders of 100 c.c. or 250 c.c. sufficed; when acid alone is used, cylinders of 500 c.c., 1,000 c.c. and even 2,000 c.c. are appropriate. Comparative experiments were made in pairs, to ensure that conditions were equal as regards strength of acid, temperature of water bath, and quality of tinplate tested.

The results of the experiments are presented in the report in a series of tables and graphs.

The "efficiency" of a restrainer was regarded as varying inversely as the volume of hydrogen involved, measured under standard conditions of temperature and pressure. An alternative method of comparison and one yielding a more scientific definition would be a comparison based upon the actual *reduction* in the volume of hydrogen obtained when the restrainer is present. This may be called the "restraining effect." Thus,

If X be the vol. of hydrogen (0° C., 760 m.m.) obtained with acid only.
Y be the vol. of hydrogen (0° C., 760 m.m.) with acid plus "restrainer."
Then X—Y will be the reduction in volume due to the action of the "restrainer,"

and the "restraining effect" is defined by the expression—

$$\frac{(X-Y)}{X} \times 100.$$

The actual "restrainers" tested comprised pickelette-acid, size (jelly), size (glue), tragon, gelatine, and cresol acid. Preliminary experiments had eliminated glucose and dextrine as practical propositions. In all the experiments 400 c.c. of 5.3 per cent. H_2SO_4 (equal to 21 grammes) and steel plate (inside sheets) of area 3,000 sq. mm., and approximate weight 4.0 grammes, were used. Taking the "restraining effect" of size (glue) as 100, the effects of the other bodies tested, in the order as given above, were 103, 99, 100, 99, 97, and nil respectively, at a bath temperature of 60° C., and 104, 97, 100, 99, 97, and nil, at a bath temperature of 77° C.

The results prove that, with the exception of cresol, the effect is very similar for all the restrainers tested. Size (glue) is of special value, as the bath remains clear at all temperatures up to 90° C., the highest temperature used in the experiments. This is an important property, as it permits the use of weaker acid in the bath. The negative result yielded by cresol was not anticipated in view of its use in froth flotation processes. "Sharps," although of high value as a restrainer, give a turbid bath, and the solution is markedly less efficient than size (glue).

THE AMINO-NAPHTHOLS.

NOTES ON THEIR SYNTHESIS AND REACTIONS.

By J. MISSENDEN and F. E. LIECHTI.

SATISFACTORY methods have been devised for the synthesis of all the fourteen amino-naphthols theoretically possible by the fusion of the naphtholmonosulphonic acids with sodamide. The reactions described below have been adjusted to suit commercial conditions, and are the only known methods for direct conversion. The several problems confronting the works chemist have been included under the respective sub-headings:—

(1) 1-*amino*-2-*naphthol:* This substance may be obtained, preferably, by reducing benzene-azo-β-naphthol with hydrochloric acid and stannous chloride. In 1900, Boehringer acquired the patent rights for a means of electrolytic production (*Brit. Pat.* No. 13,542). Beta-naphthaquinone may be obtained by the action of nitrous acid upon an acidified solution of 1-amino-2-naphthol, a reaction peculiar only to the 1 : 2 and 4 : 1 positions. The interaction of neutral solutions with cupric salts produces naphthalene-1-diazo-2-oxide (*Weiler-ter-Meer*; *Ger. Pat.* No. 155,083), although the yield is scarcely profuse, while the brightness of the azo dyestuffs is largely impaired. It is not possible to obtain the substituted amides of 2-hydroxy-3-naphthoic acid with the 1 : 2, 3 : 2, and 8 : 1 positions. Diazotisation does not take place in the presence of mineral acids.

(2) 2-*amino*-1-*naphthol* may be produced by the interaction of sodium amalgam and 2-amino-1-naphthol-5-sulphonic acid[1], or by the interaction of sodium thiosulphate and beta-naphthaquinonephenylhydrazone. The 5-derivative of the monosulphonic acid is formed upon sulphonation with anhydrous acid (10 to 15 per cent.) at 50° C. (*Sandoz*; *Ger.*

[1] The product may also be obtained from – 3 – sulphonic acid (Gattermann and Schulze; *Berichte*, 1897, xxx., 51), but the writers do not consider that, for practical purposes, such a course would be advisable. The inferiority of the sulphur position tends to retard transformation, or else render the reaction incomplete.

Pat. No. 69,228). Treated with nitrous acid in a copper solution, it is changed to beta-naphthaquinone. On agitation with an aërated solution of ammonia, a greenish liquid results, upon which may be detected a violent scum.

(3) 3-*amino*-1-*naphthol* has been prepared by the interaction of 1 : 3-dihydroxynaphthalene and ammonia solutions under similar conditions to those stated for the 3 : 1 positions. The azo-dyestuffs resemble those obtained from the amino-naphthol having the 4 : 1 position. Note should be made of paragraph (1).

(4) 3-*amino*-2-*naphthol*: The only satisfactory method known for the production of this substance is to treat 2 : 3-dihydroxynaphthalene with 30-per-cent. ammonia at a temperature of 150° C., and at a pressure of about 14 atmospheres (*Höchst; Ger. Pat.* No. 73,076). The sulphite treatment inaugurated by Badische[2] we have found somewhat unsatisfactory. Diazo-amino dyestuffs have been known to result from interaction with diazotised bases in alkaline solutions. Note should be made of paragraph (1).

(5) 4-*amino*-1-*naphthol* is best formed by eliminating the carbon dioxide from 4-amino-1-naphthol-2-carboxylic acid at a temperature of 250°—265° C. This compound will not couple with diazotised bases, but sulphonation as described in (2) produces 1-amino-4-naphthol-3-sulphonic acid. By agitating the diacetyl compound with a solution of caustic soda, the 1-acetylamino-4-naphthol (naphthacetol) is obtained. Ortho-azo-dyestuffs are produced by the diazo reaction. Nitrous acid treatment alone produces alpha-naphthaquinone.

(6) 4-*amino*-2-*naphthol* is produced by reducing 4-nitro-2-naphthol with acidified stannous chloride[3]. With diazotised bases and nitrous acid a very unstable diazo-amino compound is formed. Sulphonation produces the 1 : 3 : 4 position. Boiling with weak solutions of ammonia and acids produces, respectively, 1 : 3-diaminonaphthalene and 1 : 3-dihydroxy-naphthalene.

(7) 5-*amino*-1-*naphthol* is produced by subjecting a mixture of α-naphthol-5-sulphonic acid, naphthalene, and sodamide to a temperature of 200°—225° C. It forms monoazo dyestuffs. A good cornflower blue is obtained by the interaction of the 5 : 1-compound with diazotised α-naphthylamine-4-sulphonic acid. A cold mixture with sulphuric acid gives 1-amino-5-naphthol-6-sulphonic acid, which does not change in alkaline solutions. In the case of the sodamide process, this compound, together with the 8 : 1-compound, are the only exceptions to the general rule of the displacement of SO_3H by NH_2.

(8) 5-*amino*-2-*naphthol* is formed when β-naphthol-8-sulphonic acid interacts with naphthalene and sodamide at a temperature of 250° C. (*Brit. Pat.* No. 22,412/1905), or when α-naphthylamine-6-sulphonic acid is treated with caustic potash at a temperature of 300°—325° C. If β-naphthol-7-sulphonic acid is fused with sodamide, the 5 : 2 and 7 : 2 compounds are formed. When β-naphthol-6-or-8-sulphonic acids are used, this does not occur, the 5 : 2 position being the only one in evidence.

In a 10 per cent. solution of ammonia, 5-amino-2-naphthol produces a scintillating bluish fluid which, on admixture with a saturated solution of ferric chloride, gives a very beautiful violet colouration. The original blue liquid, if aërated, changes to a steady royal blue of considerable intensity. It forms azo-dyestuffs in dilute acetic acid.

(9) 6-*amino*-1-*naphthol* is produced by the fusion of β-naphthylamine-5 sulphonic acid with caustic alkali at about 300° C. Two monosulphonic acids may be obtained.

(10) 6-*amino*-2-*naphthol* is produced when 2-amino-6-naphthol-4-sulphonic acid is treated with sodium amalgam[4]. The addition of diazotised ortho-aminophenolsulphonic acid in alkaline solution produces monoazo-dyestuffs.

(11) 7-*amino*-1-*naphthol* is obtained by mixing solutions of 1 : 7-dihydroxy-β-naphthoic acid and ammonia, and heating to 200° C. It formes azo-dyestuffs, and gives two 2-amino-8-naphtholmonosulphonic acids on sulphonation.

(12) 7-*amino*-2-*naphthol*. (See Note 8 for the sodamide reaction.) This isomeride may be formed by heating under pressure a mixture of 2 : 7-dihydroxynaphthalene and ammonia (150° C. and at 4-5 atmospheres). It forms azo-dyestuffs, and gives 2-amino-7-naphthol-3 : 6-disulphonic acid when heated with sulphuric acid.

(13) 8-*amino*-1-*naphthol* is formed when α-naphthol-8-sulphonic acid is heated to 250° C. with naphthalene and sodamide, or when 1 : 8-diaminonaphthalene-4-sulphonic acid is reduced with 25 per cent. sulphuric acid at 150° C. under a pressure of 6 atmospheres. A saturated solution associated with diazo-nitrite gives an 8-amino-beta-naphthaquinoneoxime (*Badische; Ger. Pat.* No. 62,289) It forms azo-dyestuffs, and, in some instances[5], 8-amino-α-naphthyl sulphite has been utilised in azo-dyestuff production. Sulphonation takes place over the following range:—

H_2SO_4	Temp.	Sulphonic Acid Formed.
15 per cent.	105° C.	1-8-5 : 7 (di)
20 per cent.	100° C.	1-8-5
70 per cent.	150° C.	1-8-7

The sulphite is formed by boiling the 8 : 1-compound in a solution of sodium bisulphite.

(14) 8-*amino*-2-*naphthol* is produced by reducing 8-nitro-β-naphthol with hydrochloric acid and tin. It forms azo-dyestuffs and gives, on sulphonation, 1-amino-7-naphthol-4-sulphonic acid; but, occasionally, a disulphonic acid.

THE DISTILLATION OF AMMONIACAL LIQUORS.*

DISPOSAL OF THE SPENT EFFLUENTS.

FURTHER work has been done on this subject during the past year, but the research is still in progress, owing to the delay in erection of plant at works where novel features have been introduced that were lacking in the experimental scrubbers erected at the Hornsey gasworks, and described in last year's report. Since their erection in February, 1921, the decolourising and dephenolating scrubbers at Hornsey have successfully dealt with the whole of the effluent liquors produced in the manufacture of 2½ to 3 tons of sulphate of ammonia per 24 hours, and further improvement has now been effected in the character of the final effluent discharged—analysis indicating a volatilisation of 71 per cent. of the phenols with a reduction in the figure for "Oxygen Absorbed" of 42 per cent.

Biological Treatment of the "Dephenolated" Effluent.

Undoubtedly, however, the percentage purification effected cannot be regarded as fully coming up to expectations in view of the results obtained in the laboratory with apparatus of similar design. The improvement in the character of the liquor, *quâ* reduction in the figure for oxygen absorbed, effected by blowing with boiler-fire gases, appears to be due in great part, if not entirely, to the volatilisation of the phenols; thiocyanate and thiosulphate must be regarded as stable under scrubber conditions. All attempts hitherto made to effect the removal of these bodies by chemical action have failed, as the value of the recovered products is negligible. Attempts to deal with the effluent liquor from the ammonia distillation plant by bacterial action on specially prepared filter beds have met with a greater measure of success and encourage the belief that, could the beds be fed with an effluent from which the bulk of "phenols" had been removed by preliminary treatment in a scrubber of approved design, the final effluent discharged from the filters would be relatively innocuous in respect of phenol, thiocyanate, and other oxidisable constituents. Arrangements are now being made at the Hornsey gasworks to submit a portion of the effluent from the ammonia-distillation plant to double treatment on the lines indicated above, whereby the effluent liquor from the dephenolating scrubbers will be discharged on to a filter bed charged with specially activated material for treatment by bacterial action prior to discharge from the works. Facilities are promised for sampling the treated liquor at various stages in the process, and the results of the analyses should afford data of value for those who may be faced with similar problems.

Relation of Volume of Feed Liquor to that of Spent Effluent.

It is not the practice at gasworks or coke-oven works to measure the volume of effluent liquor discharged from the plant, but the volume of any given effluent may be taken as related, within certain limits, to that of the ammoniacal liquor distilled, and can be calculated with some approximation to accuracy if the ammoniacal content of the feed liquor be known, due allowance being made for increase of volume

* From the Alkali Inspectors' Report for 1922 (H.M. Stationery Office, 1s. 6d. net.) Continuation of the work recorded in the report for 1921 (*vide* the *Chemical Trade Journal and Chemical Engineer*, July 28, 1922 (page 105).

due to addition of lime water and admission of steam at the still. Further correction would be necessary for water introduced with acid into the saturator and evaporated therefrom, and for "devil" liquor condensed. Water vapour will also be present in the foul gases leaving the condensing system; but, with this at air temperature, the amount will be negligible. It has been usual to assume that the final effluent is related to the ammoniacal feed liquor as 150 : 100. Proceeding on the assumption that the volume of feed liquor increases by 50 per cent. prior to discharge, it is of interest to calculate the volume of effluent spent liquor for various strengths of feed liquor. Results are stated per ton of sulphate (25 per cent. NH_3) to correspond with average working conditions observed in practice, and are shown in the following table:—

Volume of Effluent Spent Liquor in Relation to Volume of Feed Liquor.

Strength of Gas Liquor.		Gallons of Liquor per ton of Ammonium Sulphate, based on 100 per cent. Conversion. NH_3 Content of S/A—25 per cent.	
Oz. Strength.	Per cent. NH_3.	Gas Liquor Used.	Total Effluent Spent Liquor Calculated for 50 per cent. Increase on G/L.
4	0.868	6,470	9,710
5	1.085	5,170	7,760
6	1.302	4,320	6,480
7	1.519	3,690	4,540
8	1.730	3,230	4,850
9	1.953	2,870	4,310
10	2.170	2,580	3,870
11	2.389	2,340	3,510
12	2.604	2,150	3,230

These figures are consistent with those given by Dr. Maclean Wilson for average coke oven practice (see Annual Report, 1921, page 10): 20,000 gallons of effluent spent liquor are stated to be discharged from works carbonising 200 tons of dry coal per day, corresponding to about 9,000 gallons per ton of S/A made.

Difficulty of Estimating the Volumes.

A correct knowledge of the volume of spent liquor produced is obviously of prime importance in any case where treatment of the effluent by blowing with fire gases is under consideration. Measurement of the feed and effluent liquors would undoubtedly be the most satisfactory way to obtain the necessary data; the collection and measurement of a large volume of boiling liquor highly charged with suspended matter, however, would require the provision of plant not always available, and the use of an alternative and simpler method is to be desired. Mention was made in last year's report of a method of calculation based on an analysis of the inlet and exit liquors concerned, taking the amount of chloride entering and leaving the system as a constant to which volumes are related by simple arithmetical calculation. Unfortunately the amount of chloride present in many liquors is small, and its estimation in complex mixtures, highly charged with organic matter, is an operation by no means easy to effect. It was thought desirable, however, to apply the method in a concrete case, and with this end in view arrangements were made at one of the larger coke oven works to submit the procedure to rigorous test under controlled conditions. The plant employed included a Holmes rectangular still with heater and bottom discharge saturator erected in 1911; the foul gases, after cooling to air temperature, are burnt in the oven flues. Three tests were made. In the first two experiments the spent and "devil" liquors were mixed in a large tank and the effluent sampled on its way to the spoil tip; in the third experiment the effluent from the still and the "devil" liquor were kept separate and the amount of the "devil" liquor was measured. The ammoniacal feed liquor in all three experiments was measured in a large boiler and the lime feed in a drum. In test No. 2 general confirmation of the correctness of the volume data was afforded by the calculated weights of thiocyanate and thiosulphate entering and leaving the system, and in test No. 3 by the figures for phenol; but the volume relationship 113 (total effluent) : 100 (feed liquor) for test No. 2 is admittedly anomalous, and in tests Nos. 1 and 3 the relationship 133 (or 134) : 100 is somewhat lower than the figure one was led to expect. Judgment is suspended, therefore, in the absence of further data obtained at a works where the volume data calculated from the analysis figures could be checked by actual measurement of the spent liquor leaving the system.

Control of Lime Feed to Still.

Speaking generally, the lime feed to an ammonia still should be related strictly to the fixed-ammonia content of the liquor distilled, a due excess of lime being provided to ensure the liberation of the whole of the fixed ammonia prior to discharge of the spent liquor from the still. At the best works periodic analyses are made of the liquor distilled and of the lime used, and due adjustment effected to ensure an excess of 10 to 20 per cent. At many works, however, such analyses occupy no place in routine testing. In general an undue excess of lime is used, which must of necessity adversely affect the production costs and lead to increased labour charges for the cleaning of stills and removal of sludge from spent liquor settling tanks (Works B below). On the other hand, deficiency of lime—as already indicated in Report, 1918, page 27—is often the cause of very serious loss of ammonia (Works D below). The divergency of practice from theory in this respect finds illustration in the following statement, the data for compiling which have been kindly supplied for publication by the management of three typical works, in all of which the process is under the care of a skilled chemist.

Lime Feed in Relation to Fixed Ammonia.

Gas Works Liquor.	Works A.	Works B.	Works C.	Works D.	
	Lime Feed.			Soda Ash Feed.	Equivalent; Lime Feed.
Period	6 months	6 months	One week	Two weeks.	
Ammoniacal Liquor Distilled:—					
Volume ..... galls.	24,189,000	2,736,000	42,770	29,660	
Fixed Ammonia:—					
Per cent. of Total Ammonia	23.5	21.0	16.3	23.3	
Total weight tons	441	31	16.2 cwts.	23.6 (cwts.).	
				As Na_2CO_3	As CaO.
Lime, as CaO—					
Equiv. to Fixed NH_3 tons	726	56	26.7 cwts.	73.5 cwts.	38.8 cwts.
Actually used, ,,	804	162	28.0 ,,	93.0 ,,	49.1 ,,
Excess used ..... ,,	78	10.6	1.3 ,,	19.5 ,,	10.3 ,,
Excess used, per cent.	10.7	190	4.8	26.5	26.5
Used, per 1,000 galls. of liquor distilled cwts.	0.67	1.18	0.65	3.15	1.65
Ammonia in Effluent Liquor,.. Per cent.	0.02	0.05	0.02	Average 0.08 (Max., 0.387; Min. 0.014).	

Note.—The results for Works A and B correspond to ordinary working practice those for Works C and D to special experimental periods, during which the lime (or soda ash) feed would be under closer supervision.

POWER ALCOHOL IN FRANCE.

DIVIDED OPINIONS ON THE NEW REGULATIONS.

A WRITER to the *Engineer*, commenting upon the putting into operation in France of the Bill requiring importers of motor fuels to purchase from the State a quantity of alcohol equal to 10 per cent. of the previous month's importation of mineral spirit, comments that it has raised so much controversy that it is difficult to see how the measure can become effective. The object of creating a "national fuel" is not only to reduce the country's dependence upon foreign oils, but more especially, for the moment at any rate, to enable the State to dispose of the huge stocks of power alcohol it has accumulated since it took over a monopoly of the purchase and disposal of spirit distilled from beet, grain and other produce. While the Union of Gas and Oil Engine Builders has been strongly supporting the Government's policy, others assert that the cost of the "national fuel" must be necessarily higher than petrol, unless the State sells power alcohol at a price considerably below the cost of production, which, indeed, it is doing at the present moment. So far as engine builders are concerned, the compulsory use of alcohol will necessitate certain modifications and adjustments that will induce users to employ French engines constructed for the purpose, and to that extent builders will be relieved of much of the competition from foreign firms. On the other hand, the stimulus given to the production of alcohol is having the effect of utilising huge quantities of beet and grain which could be more profitably employed for the manufacture of sugar and other produce.

NITRATE OF SODA.

INCREASING WORLD CONSUMPTION.

LOOKING back over the past six months, it is clear that strong efforts have been made towards the stabilisation of the Chilean nitrate industry, and with considerable success. The position to-day, viewed in all its aspects, is much more promising than at any time since before the war. Stocks have been reduced to manageable proportions, sales have been stimulated, and the outlook for the coming year, so far as is indicated by orders already booked, is favourable. Nitrate of soda is foremost in importance as a source of soil food for agricultural use, and it is, therefore, essential that its supply should not be restricted and its consumption hampered by an artificially high range of prices. The world demand for nitrogen to-day is very large, and capable of great expansion, so that it behoves the use of the long view in determining the immediate and future methods of dealing with the fertiliser situation.

Production and Prices.

Satisfactory though the position appears, it has still to be remembered that production is much below capacity-output, which factor means the financial burden of stoppage expenses being added to the price. Production for the six months ending June 30 last amounted to somewhere in the neighbourhood of 840,000 tons, which works out at about half of the possible figure. For the same period of 1922, however, the proportion was much lower at 420,000 tons, and as the estimated consumption during the coming nitrate year is variously estimated to be over two and a quarter millions tons, the number of oficinas working should be increased, with consequent reduction in working costs. On this basis, it was not unnaturally expected that producers would publish a slightly lower range of prices for 1923-24 delivery, in order to encourage still further the improving consumption. The continued incidence of the tax of 4d. per quintal due to the "Pool" as compensation for the losses sustained two years ago in connection with the huge stocks, bought at high prices by European importers, and the desire to make good for the depression of the past two years, proved too strong as factors in the calculation of the new price list, with the resulting higher level.

Scarcity of Labour in Chile.

Then, again, it is reported that labour is comparatively scarce in Chile—that is to say, the type of labour which is willing to work in the nitrate fields. The work is not attractive, and with the memory of former treatment still green, the oficinas are finding it increasingly difficult to procure men at a wage rate which will ensure substantial profits. With the more detailed organisation of labour, and the widespread feeling for a higher standard of living, the men are not content to work for the previously low scale of wages. To the Producers' Association this latter fact is probably the main reason for deciding to increase prices at a time when there is an enlarged production of sulphate of ammonia, accompanied by a widespread demand for that product.

The outstanding feature of the consumption figures for the past six months has been the increase in the quantity taken by the United States, due largely to the generally-accepted belief that an early application of the fertiliser was a means of defence against the boll-weevil, which, during the past season, has been so prevalent. Consumption in Europe was not very much larger than in the same period in last year, while in Japan and other countries deliveries inland from ports were some 70 per cent. higher. The statistics given above are for the past two years, with the figures for the corresponding six months of 1914 added for purposes of comparison.

Six Months ended June 30.		1923.	1922.	1914.
Production	tons	840,000	420,000	1,455,000
Shipments :—				
To Europe (including Egypt)	,,	495,000	103,000	831,000
,, United States	,,	484,000	141,000	310,000
,, Other countries	,,	78,000	37,000	41,000
Total shipments	,,	1,057,000	281,000	903,000
Port Deliveries :—				
In Europe (including Egypt)	,,	782,000	752,000	1,494,000
,, United States	,,	658,000	403,000	295,000
,, Other countries	,,	83,000	49,000	47,000
Total deliveries	,,	1,523,000	1,204,000	1,836,000
Visible Supply at June 30 :—				
Europe (including Egypt)	,,	171,000	228,500	416,000
United States	,,	54,000	38,000	84,000
Other countries	,,	25,000	6,000	11,000
Stocks in Chile	,,	1,008,000	1,601,000	754,000
Total supply in sight	,,	1,258,000	1,873,500	1,265,000

So far as the European consumption is concerned, there were rumours early in the year that Germany, and possibly Russia, would become important purchasers. Indeed, the Government of the former country endeavoured to negotiate the purchase of a quarter of a million tons of nitrate, but, as might have been expected, such arrangements fell through. Any faint hopes that might have been entertained by merchants were, however, scattered by the sudden slump of the German mark and the occupation of the Ruhr by the French. At the moment of writing the mark is quoted, if at all, at over a million and a quarter to the pound sterling. Currency having lost all significance, it remains to be seen what efforts will be made to resuscitate the demand in that quarter. The recent occupation of the German factories by the French, and the seizure of current stocks, which amounted, it is believed, to some 45,000 tons of synthetic products, mostly sulphate of ammonia, have resulted in a severe restriction in the output of nitrogen. There should be, therefore, a large opening for the Chilean fertiliser, could a satisfactory basis of payment be arranged. Altogether only about 10,000 tons were sold into that market, and, as a leading broker puts it, "under existing conditions it appears unlikely that any important quantities will be sold there." Consumption in the United Kingdom, although gradually rising since 1921 on agricultural account, is not of a nature to enthuse merchants in this country.

Time Extension of the Producers' Association.

An interesting event which took place during the half-year under review was the decision to extend the life of the Producers' Association for a further six months until June 30 next. There were some dissentients to the scheme for continuation, but a stringent boycott was imposed, with the result that one of the Chilean producers has given his consent to the new arrangement, and the early adhesion of the others is expected. It is generally thought among producers that a further term of five years of life for the Association would benefit the industry considerably. Complete unanimity on this point is not obtainable, however, but when it is considered that the idea is supported strongly by the Chilean Government, upon which many of the producers are dependent for financial support, there is little doubt that it will ultimately come to pass.

OUR BOOKSHELF.

Chemistry, Inorganic and Organic. Charles Loudon Bloxam. London: J. and A. Churchill; 36s. net. (10th edition).

Ten years have elapsed since the last edition was published, and very strenuous work has been devoted successfully to the construction of an edition which would worthily maintain the high reputation of its predecessors. Bloxam's was always a very safe work of reference and commanded more than passive esteem amongst chemists and technologists. A great point in its favour is the very wide range (inorganic and organic) it has always managed to cover in the single volume without any undue compression.

Theoretical and Applied Colloid Chemistry. Ostwald and Fischer. London: Chapman and Hall, Ltd.; 12s. 6d. net.

This work, now in its 3rd edition has done much to promote and stimulate a better appreciation of colloid phenomena. There can be no doubt about the modern demand for knowledge in this direction and the increasingly important part it must take in the general scheme of scientific and industrial progress. Technical Applications occupy nearly 70 pages, brimful of practical detail, simply expounded. Reference to the region of colloid dimensions as "the world of neglected dimensions" is a happily conceived phrase, which is a key-note representative of the spirit and aspirations of this very excellent volume.

BRITISH DYESTUFFS CORPORATION, LTD.

ANNUAL GENERAL MEETING.

THE fourth ordinary general meeting was held in Manchester on Tuesday, July 10. Sir William Alexander, K.B.E., chairman and managing director, presided over a large attendance of the shareholders. Mr. D. R. Mackay (secretary) read the notice convening the meeting and the report of the auditors.

The Chairman, after furnishing a comparison between the balance-sheet before the meeting and that of the previous year, proceeded: "We will now turn to the year's results as shown on the directors' report. The balance of profit (after providing a total of £411,000. for depreciation and crediting the further amount estimated to be recovered in respect of excess profits duty) amounts to £102,656. The balance of loss carried forward from the previous period was £803,355. This leaves to be carried forward to next year a deficit of £700,699. The volume of trade in the home market has shown a substantial increase, which your directors have endeavoured to stimulate by reducing prices —in many instances even below the present level of cost. The possibility of trade with overseas markets has been very limited, and business has been carried on under great difficulties. Although we are preserving a position in the more important foreign markets it is more with a view to development in the future than to the realisation of any immediate benefit. So long as colours from German sources can be offered in neutral markets at prices against which no country with a stabilised currency can compete, I am afraid this unsatisfactory condition of our overseas trade must continue.

Our trading results for the year ended October 31, 1921, were affected by two items of an exceptional nature—namely, the large amount required to be written off stocks to reduce them to current market prices, and a substantial amount estimated to be recovered on excess profits duty. The further amounts brought into the current year's accounts in respect of these two items are comparatively small, and if we take the two trading periods and ignore in both cases the amounts credited for refund of excess profits duty and the amounts written off stock values, we find that the trading results for the year ended October 31, 1922, show an improvement of £778,000. as compared with the previous year. I think you will agree that this result, which has been obtained notwithstanding an average reduction of 17½ per cent. in our selling prices, constitutes the best justification for the policy adopted by your Board and reported to you at the last ordinary general meeting. I propose briefly to recapitulate the manner in which we have endeavoured to deal with the problems we were then called upon to face.

The Year's Achievements.

I shall first refer to the excessive stocks of raw materials, stores, and colours accumulated in previous periods. With the exception of certain stocks of engineering stores, all these surplus stocks have been liquidated. This step, by releasing a large amount of capital previously tied up, has contributed to the strengthening of our financial position, with the result that we have to-day a total of over £2,000,000. in cash or invested in readily-realisable securities. For some time past all items of expenditure have been periodically reviewed with the object of securing reductions and bringing our standing charges into closer relation with the present restricted volume of trade. It is satisfactory to report that the economies effected have contributed in no small degree to the improved trading results which are now before you.

In research and technical development we have continued the policy of concentrating our efforts mainly on raising the standard and quality of our production and improving our processes of manufacture, through which our trading operations have materially benefited. This improvement arises not only from the application to works processes of the results obtained in our research laboratories, but also from the more intimate knowledge of plant operations which our process chemists are acquiring. I am convinced that it is to this cause we must look more and more in the future to secure economical working and improved efficiencies. A loyal and contented staff, working together with a common aim, is essential to our plans, and during the year we have consolidated our technical staffs and given the new organisation a fair chance of establishing itself.

Trading Prospects.

In my speech of last year I pointed out that the main hope of obtaining a reasonable return on our capital must lie in our ability to keep our plants well employed. I am afraid that I must repeat this warning. The present volume of trade is still too restricted to allow our plants to be used as economically as is possible, and until normal conditions of trade are restored in the consuming industries no marked improvement in our trading results can be anticipated. In the meantime, your directors are continuing to conserve the financial resources of the undertaking and to effect such further economies as are possible in both productive and administrative charges.

To one item of expenditure I desire to make special reference. During the four years ended October 31, 1922, your Corporation and its associated companies have spent a total amount of over £400,000. on research. Much of this expenditure has been incurred in establishing the constitution of colours not previously made in this country, and in working out processes for the manufacture of the new and necessary intermediate products. This field has now been well covered, and expenditure in this direction is diminishing. Henceforth our principal aim will be to utilise our research organisation for the purpose of securing better efficiencies and increased yields of products in actual manufacture and of introducing such new colours as are in steady demand by the consuming trades. It is with this object that the consolidation of our technical staffs has been carried out, and your directors feel that the time has come when further economies can be effected in our research department. We are fully alive to the necessity of research, not only for the improvement of current operations, but for the working out of new problems which, although not immediately remunerative, will, it is hoped, enable us, as time goes on, to take a more independent line in the development of dyestuffs and allied organic products. I promise you that this aspect of research work will not be neglected in any steps which are taken to effect economies.

Effect of the Ruhr Occupation.

A word now on reparation dyes and the effect of the Ruhr occupation. In September, 1922, the Corporation was appointed agents for the Board of Trade for the distribution of dyestuffs received under the reparation clauses of the Treaty of Versailles. The organisation established for importing, warehousing, and distributing such dyestuffs is working efficiently and we have every reason to state that it has given satisfaction to consumers and others interested. Considerable and changing difficulties have been experienced in maintaining contact with German suppliers since the occupation of the Ruhr valley by France early this year. So far, however, we have succeeded in obtaining the great bulk of the supplies awaiting delivery, and have every hope that the balance still available for us will be received. Very considerable disturbance to the German dyestuff industry has been caused by the French occupation. Whilst some works have been able to maintain output others are entirely closed, and it is estimated that German production has already been reduced by over 50 per cent. Difficulties are increasing, and it is impossible to forecast what the end may be. The position has become more confused by the action of France and Belgium in seizing large stocks of dyestuffs, which have been conveyed to French and Belgian territory. An indiscriminate distribution of these dyestuffs might materially affect the interests of your Corporation, and strong representations, which are not being disregarded, have been made to the Government on the difficulties and dangers of the situation.

The Prices of Dyestuffs.

I now turn to a matter to which prominence has recently been given by consumers and others—namely, the prices charged for our dyestuffs. At our last meeting I stated that our average price was then 3s. 5d. per pound. The average price to-day is 2s. 6d. per pound—a reduction of 25 per cent. Your directors consider that the demands of the consumer for price reductions have been met to the utmost of the resources of the company. The consumers, through their organisation, the Colour Users' Association, have expressed disappointment that we cannot go further, and they have suggested that we should take a bolder line and reduce prices to a level of not more than three times the pre-war price as a maximum on each individual colour, relying upon the Government to make good any loss by a grant in aid from the proceeds of the sale of reparation dyes or by a direct subsidy. Discussions have been pro-

ceeding for some time past with the Council of the Colour Users' Association, but, unfortunately, we have not been able to see eye to eye with them.

I believe I am correctly stating the attitude of the large majority of consumers when I say that they are as determined as ever to have a dye-making industry in this country as security against such a position as now exists owing to the disorganised state of Germany. Where we part company is in the contention they put forward that a three times pre-war factor as a maximum is sufficient not only to cover the economic advance in the cost of production, but also to yield a handsome contribution towards the development and establishment of the industry.

The Three Parties to the Industry.

I think that we are all agreed that no industry of the complexity of ours can be established without some sacrifice on the part of those most vitally interested in it. In our case there are three parties with a common interest, the Government, the user, and the shareholder. The industry is of interest to the Government in that it provides the only school in which a large and competent body of chemists can be trained in the technology of organic substances. The industry is of interest to the user because it is the only security he has against a repetition of the position in which he found himself in 1914. The industry is of interest to the shareholder because he has a large financial stake in it. It is only by maintaining the common interest of the three parties—the Government, the user, and the shareholder—that any progress can be made, and it is imperative that there should be equal readiness to contribute towards that progress.

So far the contributions of the Government have been, first, the subscription of 1,700,000 preference and preferred ordinary shares in the company, and, second, the passing of the Dyestuffs (Import Regulation) Act prohibiting for a term of years the importation of dyestuffs except under licence. It is important to remember that this Act was passed to put into effect the declared policy of each successive Government since 1914, which policy took concrete form when in May, 1918, the President of the Board of Trade announced in the House of Commons that protection would be afforded to the dyestuffs industry by means of a control of imports.

The contribution of the consumer of dyestuffs has been assent to a restriction of access to foreign sources of supply through the operation of the Act. This assent was given subject to the right to demand a licence for importation in cases where the prices quoted by the home manufacturer placed the consumer in an unduly disadvantageous competitive position.

The Shareholders' Contribution.

The contribution which the shareholder in this Corporation is making towards the establishment of the industry is one which is apt to be entirely overlooked. Those who subscribed £5,000,000. of new capital are entitled to expect under normal conditions of trade an adequate return on the capital so invested. Let us examine the return which the shareholder has actually obtained from 1914 onwards. The Corporation and its predecessors rendered an invaluable service to the colour-using industries in this country—a service which enabled these industries not only to maintain their position in the world's trade, but to make profits which were certainly not less than those made in pre-war periods. From 1914 to date the shareholders of British Dyes, Limited, of Levinstein, Limited, and of British Dyestuffs Corporation, Limited, have in all received by way of dividend a total sum equivalent to 2 per cent. per annum on the average share capital employed, and are now faced with a trading loss amounting to more than £700,000. (a sum slightly in excess of the total dividends previously paid) and also with the necessity of continuing to set aside for some time to come large sums for depreciation, research, and development. During the same period an expenditure of more than £7,000,000. has been incurred in the provision of land, buildings, plant, and machinery for development purposes.

It is true that the bulk of this expenditure took place during a period of exceptionally high costs, but I ask you to remember that this expenditure would not have been entered into had it not been considered by all parties concerned that the need was urgent and that heavy expenditure, at whatever cost, must be immediately faced if a dyestuffs industry was to be established in this country. By way of provision for this abnormal cost of construction and for the heavy depreciation inseparable from chemical plants a total sum of £3,500,000. has been set aside to date. Much of this sum might have been legitimately distributed in past years by way of dividend. The sounder view of working for the ultimate establishment of the business on the basis of a moderate capitalisation has been taken, and I think with these figures before you you will agree both as shareholders, and many of you as users, that the shareholders have more than done their part in assisting to establish the industry.

The Suggested Maximum Price for Dyestuffs.

I will now return to the proposals of the Colour Users' Association to establish a three-time pre-war factor as a maximum price at which dyestuffs should be sold. It is not easy to ascertain the pre-war price of dyestuffs owing to the practice adopted by the German firms of granting price concessions to large consumers, but we have prepared a statement showing what we consider to be the average pre-war price of each of the colours now sold by us. This statement has been furnished to the Council of the Colour Users' Association, and, although they may not accept every one of the prices we have adopted, I think they will agree that we have endeavoured to be as impartial and as fair as possible. Working on the basis of this statement, we estimate that the application to our present rates of a three-time factor as a maximum would adversely affect our trading results to an extent of something between £300,000. and £350,000. The effect of the application of this factor to future trading results is best realised when I tell you that by its adoption the Corporation could double its turnover and still show no profits available for distribution amongst its shareholders. That, ladies and gentlemen, is a situation which we, as directors, cannot recommend our shareholders to accept.

It may be replied that this result arises because we are either inefficient in our production or extravagant in our management. This I deny. Since our last meeting we have placed on the market, in addition to 21 improved brands, no fewer than 45 new colours equal to the best German type. We have no reason to feel ashamed of the progress we have made in securing increased efficiencies, but you cannot, in such a highly complicated industry as ours, build up a technically perfect organisation within a few years. On the administrative side we have rigidly curtailed expenditure, and any further economies that may still be effected (and there will be no relaxation of our efforts towards this end) would make a relatively small contribution towards the reduction of our costs.

Manufacturing Costs: A Comparison.

I do not think that the magnitude of the increase in costs of manufacture in the dyestuff industry to-day as compared with pre-war costs is fully realised. The chairman of the Colour Users' Association has kindly furnished me with a copy of the speech recently delivered by him to the Council of that Association. In that speech he gives the present wholesale price index figure at 61.4 per cent, above pre-war rates, and deduces from this that the colour-user is not unreasonable in asking that the British manufacturers' prices should not in any instance exceed 200 per cent. above pre-war prices. The wholesale price index figure does not, unfortunately, assist us in considering the advance in our manufacturing costs. I have had prepared a comparison between pre-war and present prices for the principal items entering into our costs, and these I will give. Raw materials, based on a weighted average of the 25 principal raw materials used, show an advance of 133 per cent. over pre-war costs. Salaries of our chemical, technical, and engineering staffs show an advance of 174 per cent. Wages show an advance of 142 per cent. Coal, services, stores, and general charges show an advance of 130 per cent., making an average advance of 135 per cent., which is more than double the wholesale price index figure quoted by the chairman of the Colour Users' Association. A factor of 2.35 times pre-war is, therefore, required to cover these increases.

There is a further point involving an increase in the cost of manufacturing dyestuffs throughout the world which cannot be ignored. Before the war the German dyemaking firms controlled directly or indirectly over 90 per cent. of the world's production of dyestuffs, and having the whole world as their market, they were able to keep their plants in continuous operation. Since the war dyestuffs plants have multiplied, particularly in France, the United States, and this country, and no group of dye manufacturers in any country can in future expect to obtain such

a predominant share of the world's trade as was enjoyed by the German firms in the past. Standing expenses in the dyestuffs industry are heavy, and in comparing pre-war with present costs some allowance must be made in all dye-producing factories for the fact that plants cannot be worked as intensively as in pre-war days, and costs must be fixed on a production materially below available capacity. I estimate that even in a period of normal trade an increased factor of at least .35 is necessary for this purpose, and adding that to the price factor of 2.35 previously given we obtain a factor of 2.7 times the pre-war price which is required to cover the increased cost in present manufacturing conditions as compared with those prevailing before the war.

Objections to a Rigid Price.

The factor offered by the Colour Users' Association is a three-time maximum factor with no minimum. A number of our cheaper colours are at present sold below this price factor, and if we take our actual sales and apply to them the three-time factor or the present selling price, whichever is lower, we obtain an average factor of 2.75. Therefore, by offering us a three-time factor as a maximum the Colour Users are only offering a factor sufficient to cover the difference between economic conditions of cost to-day and those prevailing before the war. They are giving us nothing towards the establishment and building up of the industry.

Many colours can be, and are being, sold within the factor suggested by the Colour Users' Association. Many other colours will, with a return to normal working, automatically come within this factor limit, but there are many colours which, owing to heavy expenditure on research, works trials, and the lack of technical experience, we are unable to produce at a price calculated on this basis. To sell them on these terms would mean a heavy financial loss to the Corporation and an unreasonable sacrifice on the part of our shareholders.

The high degree of technical skill attained by the Germans was only reached through many years of research and continuous operations of very large plants. Our experience in this sense only began after the war, and we have, unfortunately, owing to the depression in trade, not been in a position to work our plants in such a continuous manner as to enable our chemists to acquire the detailed knowledge and the technique of the small adjustments in methods of operation which often mean the difference between success or failure to produce at a low cost. Further, it must be remembered that in 1914 keen competition existed between the two groups which now constitute the German Interessen Gemeinschaft, and this led to the prices of ordinary ranges of standard colours being cut to a level which yielded little or no profit. For the bulk of their profits the German firms relied upon specialities, some of them new colours and some of them products outside the dyestuffs industry proper, such as the heavy chemical production of the Badische Company, the serums and fine drugs of Meister Lucius and Brüning, and the photographic products of the Bayer Company.

These undertakings, secure in their main purpose, have had time and energy to spare for new fields of manufacture. The strength of *our* technical and research staffs has of necessity been given to the production of the colours immediately needed by customers. *We* must first be satisfied as to the range and quality of our colours, and as to the efficiency of our processes, on which our very existence depends. Developments on new lines, for which we have both the ideas and the ability, will follow.

The Licensing Committee.

I must here refer to the Licensing Committee appointed under the terms of the Dyestuffs (Import Regulation) Act. This Committee consists of five nominees of the user, three nominees of the maker, three independent members. You will see, therefore, that the makers, in order to secure a majority on any question affecting their interests, must have the support of all the independent members.

The Licensing Committee is the battle-ground of the user who desires to import a colour and the maker who objects to its importation on the ground that the equivalent is already manufactured by him. Both makers and users are assisted by a technical staff, and the bulk of applications put forward are readily dealt with by agreement between the various interests.

In September last, as a temporary measure, the Licensing Committee agreed to grant applications to import where the British prices were more than three times the pre-war level or were higher than the current foreign prices. In other words, the British maker was given the opportunity to take the business, either at the foreign price quoted or at three times the pre-war price, whichever was higher. The nominees of the makers agreed to this temporary arrangement on the understanding that financial assistance, in some form or other, would be forthcoming from the Government. The expectation has not been fulfilled, and the makers are in many instances faced with the alternative either of selling their products at a loss or refusing orders and ceasing to manufacture. Under these circumstances we have advised our nominee on the Committee to withdraw our assent to the arrangement made, and to request that all applications be dealt with strictly in accordance with the procedure laid down under which the user must prove that the price quoted by the British maker places him in an unduly disadvantageous competitive position.

New Colours: Effect on German Prices.

Your directors regret exceedingly that they have been compelled to take this step, but when I give you a few examples of the manner in which the present arrangement has operated I think you will agree that, failing the compensation which has not up to now been forthcoming, we were unable to take any other action. In May, 1920, we introduced on the market an important acid colour at 25s. per pound in competition with the German type then selling at the same price. In March, 1921, we introduced an improved brand, slightly superior to the German type, and were able to reduce the price to 13s. 6d. a pound. We are to-day prepared to accept bulk orders for this colour at 8s. a pound, although at this figure we are barely covering actual works cost. Licences for the importation of the equivalent foreign colours are being applied for to-day at prices varying from 4s. 8d. to 6s. 6d. a pound. We have, consequently, been compelled to close down our plant and cease manufacture.

In March, 1922, we introduced a vat colour, of which we are the only manufacturers in this country, in competition against the German product which was then selling in powder form at 68s. per pound. Our colour, which is equal in strength and properties to the German type, but admitted by consumers to be rather superior in shade, was introduced at 45s. per pound. The effect of our entering the market has been to reduce the German product to 34s. a pound. In 1919 we introduced in response to a general demand by users, a direct cotton colour at 12s. 3d. per pound. We have offered to take contracts for large quantities at 4s. 3d. per pound—a price considerably under works cost. Applications to import the German equivalent at 2s. 9d. per pound have been put into the Licensing Committee.

Those, and many other examples which I could give, are new products on which a large amount has been spent on research and development and on the provision of plant. In the case of one important colour alone the special plant to be provided cost over £80,000. The effect of our policy has been to secure to the colour user an enormous reduction in price, which he could not have obtained in the absence of our competition. The result to ourselves has been heavy expenditure, on which we are unable to obtain any return owing to the prices which the German firms are now quoting, assisted as they are by the almost vanishing value of the mark as a medium of international currency.

The application of a three-time pre-war factor is quite insufficient to cover the cost of producing a new product, and under these conditions it is obvious that further development of the industry must come to a standstill. We suggest that colour consumers generally should agree to stabilise, for a reasonable period, the price they are willing to pay for a new British product, provided such price is not in excess of that quoted by the foreign maker prior to the introduction of the British product on the market. A strong opinion in this direction has already been expressed by an important section of colour users.

Capitalisation.

Many shareholders and colour users have expressed the opinion that, in view of the heavy debit balance carried forward on trading, and to the large amount still carried in our accounts for goodwill, trade-marks, and preliminary expenses, a scheme should be formulated for reducing the capital of the company. In some cases it has been further urged that, in spite of the large amounts written off to date, the book value of our fixed assets is excessive, and in

the event of a reconstruction they should be still more drastically written down. I may say at once that your directors do not consider the present time opportune for considering any scheme of reconstruction. From the accounts placed before you, you will see that, including the debit balance on trading account, we have in non-tangible assets a sum of something approaching £2,000,000., which will require to be dealt with in formulating any scheme of reconstruction. With regard to our fixed assets, these stand to-day in our books at a figure of under £3,500,000. Your directors will not hesitate to come before you with a scheme, when they consider the time ripe, for wiping out the heavy debit balance accumulated on trading and dealing with the value of goodwill and patent rights in respect of which deferred ordinary shares were issued to the shareholders in the merger company.

At the present time it is impossible to see far ahead and to estimate the conditions under which we will require to carry on our business in the future. For the information of the shareholders, I may state that the Corporation's financial position to-day is such that, if we went into voluntary liquidation, we estimate that we have sufficient assets in cash, investments, book debts and stocks, after paying off our trade creditors, to give every preference shareholder 20s. in the pound. This could be done without taking any value for our land, buildings, plant, and machinery, which have cost £7,000,000, and which, as I have already told you, stand to-day in our books at £3,500,000, or one-half their total cost. The proceeds from the disposal of these properties would be available for distribution amongst the preferred ordinary and deferred ordinary shareholders.

Progress and Prospects: A Summary.

I apologise for trespassing at such length on your time and indulgence, but your directors desire to be frank in every detail, both to shareholders and consumers, and before closing I should like to summarise very briefly the position as we find it to-day.

(1) The dyemaking industry has now been definitely established in this country. (2) The quality of our production is equal to that of the best German types. (3) In conjunction with other British makers we are able to satisfy the bulk of the requirements of the colour-using industries. (4) The majority of the colours not yet made in this country are of a special type requiring not only close research, but in many instances the provision of special plants. Before makers can be induced to incur the heavy expense involved in the production of these colours there must be security against competition from foreign sources of supply. I have already suggested that consumers should in these cases agree to stabilise prices for a reasonable period. In the absence of such support you may take it that no British maker can afford to face the heavy loss which the introduction of a new colour must inevitably entail.

(5) The British industry has given to the consumer a security of supply which was lost to him in 1914, and which is enabling him to face with equanimity the present uncertainty of foreign supplies. (6) The fixing of a three-time pre-war factor as a maximum price without other compensation would ultimately involve the closing down of plants and the cessation of the manufacture of many of the more important dyestuffs placed on the market by British makers in recent years. In the main, only the cheaper grade of colours could to-day survive this test. (7) The dyestuffs industry is the only industry which, during times of peace, is capable of equipping and maintaining an adequate body of chemists trained in the methods of organic chemistry.

(8) This country has in the past built up its industrial supremacy and its national security by maintaining a lead in the iron, steel, and heavy chemical industries. To maintain this position we are now compelled to take a leading part in the exploitation of the organic chemistry field. Without the protection afforded by the Dyestuffs (Import Regulation) Act the dyestuffs industry in this country, under present world conditions, could not survive. With the adherence without compensation to a price factor of the rigid nature proposed by the Colour Users' Association, its development must cease, and the industry will be slowly but surely strangled. (9) Security, with adequate safeguards against inefficiency is essential, and we claim on the strength of our performance and resources that both the Government and the colour-using industries shall take their share in providing this security.

(10) The Corporation, and I doubt not other British dyemakers on their side, are prepared to throw the whole of their energies into the development of the industry so that they may be prepared to meet the world competition which will arise from stabilised conditions of trade and currencies.

I should like just to say a word or two to express the grateful appreciation of the Board, and, also, I am sure, of the shareholders, of the devotion and labours of all our staff during the past year.

I now move "that the Report of the Directors and the Statement of Accounts for the year ended October 31, 1922, be received and approved."

Mr. Parker Smith objected to the non-disclosure in the accounts of the amount estimated to be recovered in respect of excess profits duty. He further criticised the constitution of the Board as containing no representative technically competent to control the manufacture of dyestuffs, and expressed his views as a colour user on the high prices charged for the Corporation's products. In his opinion, under competent management, there was no need to charge more than three times the pre-war price for any colour.

The Chairman, in reply, stated that the amount which had been taken credit for in respect of excess profits duty was less than the amount required to be written off for fall in stock values, and that he had already furnished a comparison between the two trading periods, excluding the amount received for refund of excess profits duty, and the amount required to be written off for stock depreciation. There had been no unnecessary writing down of stocks. As the trading position was to-day, he would not be ashamed to come before them with his report next year.

Th motion adopting the report and accounts was passed with three dissentients.

Mr. G. V. Clay was re-elected director, and Messrs. Thomson, M'Clintock and Co. re-appointed auditors.

A vote of thanks to the chairman, moved by Mr. H. Sutcliffe Smith, chairman of the Colour Users' Association, and seconded by Mr. G. Collis, was carried.

LEGAL INTELLIGENCE.

BRITISH-PRODUCED OIL.

George Edward Heyl.

The debtor has been closely associated with the oil industry for a number of years, and his affairs came before Mr. Registrar Hope, at the London Bankruptcy Court, on Wednesday, July 4, on the re-hearing of his application for an order of discharge. He was adjudged bankrupt on March 13, 1918. He had been engaged in inventing different processes for and in research work in connection with the production of oil from British natural resources, and a company was ultimately formed to finance his undertaking for the manufacture of oil at Barking and Corton. In May, 1917, the Rapid Distillation and Power Company, Limited, with a nominal capital of £1,000,000, was formed, and it acquired his entire interests in his business and inventions at Barking and Corton. According to the trustee in bankruptcy the ranking indebtedness amounts to £50,407., and on May 4 the debtor applied to the court for his order of discharge. The Official Receiver then opposed the application on the grounds that the debtor's assets were not of a value equal to 10s. in the £ on the amount of his unsecured liabilities, and that he had been guilty of misconduct in failing to attend his adjourned public examination on July 25, 1919. The court upheld these submissions of the Official Receiver, and suspended the debtor's discharge for one year. In an affidavit that had since lodged the debtor said that his assets had paid a dividend of 6s. 6d. in the £, and a further 3d. or 4d. might be paid. He asked the court to revoke the order of May 4 and to grant him an immediate discharge subject to his consenting to judgment in a sum of £200, of which £100 would be paid forthwith and the balance in six months. Mr. Registrar Hope granted the debtor this application, saying that the £100 would have to be paid before he signed the order of immediate discharge.

Tin-plate Exhibition.—The Welsh plate and sheet manufacturers are holding a special exhibition of their products at their bureau at 3, Northumberland Avenue, W.C.

ITEMS OF INTEREST.

Bank Rate Increased.—On Thursday of last week, the Bank rate, which for the past 51 weeks, has remained at 3 per cent. was raised to 4 per cent.

British Cyanides Company.—An illustrated booklet has been published by the British Cyanides Co., Ltd., containing some excellent views of their extensive works, and considerable detail concerning their organisation and general aims is given.

Research Endowment.—The Council of the Royal Society have decided to use the recent gift by Sir Alfred Yarrow of £100,000 in founding a number of professorships, the holders of which will be expected to devote their whole time to scientific research.

Trade Inquiry from Canada.—The Montreal Branch of an important British firm of engineers desire to act as agents for saltcake. Further information can be obtained from the Department of Overseas Trade, 35, Old Queen Street, S.W.1, quoting reference number 7.

Blast Furnaces Close Down.—Two blast furnaces which were started at Palmer's Works, Jarrow, about three months ago, on the making of hematite, have been closed down again owing to depression in the iron and steel trades. A third furnace had also been made ready for lighting.

Imports of Dyestuffs.—During June applications for licences under the Dyestuffs (Import Regulations) Act, 1920, numbered 512, of which 393 were from merchants and dealers. Of the total applications 80 per cent. was dealt with within four days of receipt.

Coke Plant Explosion.—An explosion which occurred in the coking plant of the Birchenwood Colliery, Kidsgrove, on Tuesday caused the death of Richard York, of Stoke-on-Trent. The explosion took place in the exhauster-house, in which York was the only person present at the time. The explosion was followed by a fire, which was extinguished by the works fire brigade.

U.S. Tariff on Calcium Arsenate.—A report from Washington states that the interests endeavouring to obtain the placing of arsenic on the free list have abandoned the idea of appealing direct to the President. Although a Bill is to be introduced into Congress in December next, to place the product on the free list, it is said that there is little hope of the measure receiving favourable attention. The present import duty is 25 per cent.

Overseas Trade in June. — Preliminary figures of the overseas trade of the United Kingdom during June show that imports amounted to £89,307,683, as compared with £89,478,996 in the preceding month. Exports of produce and manufactures of the United Kingdom amounted to £62,883,559, as compared with £71,554,864, and re-exports of foreign and Colonial merchandise amounted to £10,954,932, as compared with £11,773,426.

Preservatives in Food.—The Minister of Health has appointed a committee consisting of Sir H. C. Monro (chairman), Professor W. E. Dixon, Sir A. D. Hall, Dr. J. M. Hamill, Mr. O. Hehner, Professor F. G. Hopkins, Dr. G. R. Leighton, Dr. A. P. Luff, Dr. C. Porter, and Mr. G. Stubbs, to report whether the use of materials for the preservation and colouring of food is injurious to health; and, if so, in what quantities does their use become injurious; and whether it should be required that the presence of such materials and the quantities present in food offered or exposed for sale should be declared. The secretary of the committee is Mr. A. M. Legge, of the Ministry of Health, Whitehall, London, S.W.

University News.—The following have been appointed by the Council of Manchester University to be Assistant Lecturer in Chemistry: Mr. E. L. Hirst and Mr. G. N. Burkhardt.—Professor John Reid, Professor of Organic Chemistry in the University of Sydney, has been appointed to the vacant Chair of Chemistry in the United College and to the Directorship of the Chemistry Research Laboratory at St. Andrews University, in succession to Professor Robinson. The Council of Liverpool University, on Tuesday, decided to use the bequest of the late Professor Campbell Brown of the residue of his estate, approximately £36,000, in founding a Campbell Brown Chair of Industrial Chemistry and a Campbell Brown Fellowship for senior and honours chemistry students. The balance of the bequest will form a fund for the provision of entrance scholarships.

Explosion of an Oxygen Cylinder.—An oxygen cylinder exploded in one of the operating theatres at King's College Hospital, Denmark Hill, on Monday. The explosion, which caused damage to the theatre estimated at several hundred pounds, was caused, it is thought, by the excessive heat.

Motor Fuel from Potatoes.—A company has been formed in Guadeloupe for the purpose of manufacturing motor fuel from sweet potatoes. It is expected that 5,000 litres will be distilled daily, and the product will be available for local consumption in October or November next.

British Coal Output.—During the week ended June 30 the coal output from the mines of Great Britain was 5,400,700 tons, compared with 5,588,200 tons for the previous week and 4,530,000 in the corresponding week of last year.

Unclaimed Cask of Arsenic.—An announcement in the personal column of *The Times* states that unless the cask of arsenic, the name and address of the owner of which is unknown, is claimed and all charges paid before Monday next, the proprietors of Rennies Wharf, Ltd., of 60, Holland Street, E.C., will sell same to defray expenses.

Oil in Spain.—In the valley of Burunda at Alsásua (Navarre), investigations of a Spanish engineer have confirmed the existence of a hitherto unknown petroleum zone, states a Reuter report. The geological formation of the zone indicates deposits which, judging by all appearances, may prove to be of great importance. The land belongs to the Compañia Franco-Española de Petróleos of San Sebastian, which proposes to undertake boring operations at once.

Belgian Radium Producers' Progress.—At the general meeting of the Union Miniere du Haut Katanga, held in Brussels, on Monday, Mr. J. Jadot, the president, stated that the accounts showed a net profit of 20 million francs. Dividends of 35 francs (less tax) on the ordinary shares and 30 francs net on the preferred shares were declared. The extraction of radium from uranium ore is proceeding at the Oolen Works in Belgium, which have been established with great success.

Fire.—Damage estimated at £250. was caused on Monday by an outbreak of fire in the works of Messrs. Turnbull and Co., wood distillers, 16, Great Eastern Road, Glasgow. A corrugated iron shed and a brick building were damaged, and a quantity of wood was destroyed. During a fire at Messrs. Marshalsea Brothers' motor works at Taunton on Wednesday, cylinders of oxygen exploded with great force, the damage being estimated at over £10,000.

Coal-dust Explosion Experiments.—The Mines Department, in a letter to the Secretary of the Institution of Mining Engineers, announce that the Safety in Mines Research Board propose to arrange for a series of coal-dust explosion experiments at the Experimental Station, Eskmeals, Cumberland, with the object of impressing upon mine-workers the importance of the coal-dust problem. The demonstration will be made each Sunday from the 15th inst. to September 30 (inclusive).

Clouds and Smokes.—An important new book entitled "Clouds and Smokes; the Properties of Disperse Systems in Gases," will shortly be published by Messrs. J. and A. Churchill. The author is Dr. W. E. Gibbs, chief chemist to the Salt Union, Ltd. There will be about 30 illustrations. The author describes the various ways in which such disperse systems in gases can be formed, and deals fully with their mechanical, thermal, optical and electrical properties, and the conditions which determine their stability. This information is then applied to the practical problems of meteorology, fume condensation, gas filtration, the manufacture of substances in a finely-powdered condition, and the use of smoke in warfare.

Personal.—Dr. Francis William Aston, who has rendered valuable contributions to the science of physics during the past ten years at Cambridge, was made an honorary LL.D. on Saturday last at Birmingham University Degree Congregation. Dr. Aston graduated at Birmingham, and has already been awarded the Nobel Prize.—Mr. Hugh F. Marriott, who is leaving for Australia this week to attend the Pan-Pacific Congress as a representative of the British Government and various professional and scientific institutions, announces that he has ceased to be actively concerned in the reorganisation of the Magadi Soda Company.—Dr. F. G. Banting, of Toronto University, the discoverer of insulin, has been awarded an annuity of $7,500, to permit him to devote his life to medical research.

New Czechoslovakian Glass Company.—A new company —under the title of "Resista"— has just been formed at Prague, Czechoslovakia, to manufacture the so-called unbreakable glass invented by Dr. V. Horak at the time he was general manager of the Cavalier Glass Co., at Sazava Buda, which company manufactures a somewhat similar glass under the trade name "Silex." The new Resista Co. is capitalised at 1,200,000 crowns (6,000 shares at 200 crowns each).—*U.S. Com. Report.*

Salt Production in the U.S.—According to a statement issued by the U.S. Department of the Interior, compiled from statistics collected by the Geological Survey, the quantity of salt produced and marketed in the United States in 1922 (classed by the varieties) was as follows:—Evaporated, 2,276,683 short tons; in brine, 2,569,042 short tons; and rock salt, 1,947,124 short tons. The total value was $27,461,839. These figures show an increase of 36 per cent. in quantity but of only 12 per cent. in value over those for 1921.

Chemicals for Cuba.—His Majesty's Consul at New York reports that a local firm are desirous of purchasing the under-mentioned chemicals in England, primarily for sale in Cuba:—Refined pyridine, amonium carbonate (lump and powdered), castor oil of the No. 1 or medicinal grade, whiting (Blanco Espana), tartaric and citric acids, naphthalene flakes and balls. British firms desirous of receiving further particulars regarding this inquiry should apply to the Department of Overseas Trade, 35, Old Queen Street, S.W.1, quoting reference 20039/F.W./C.C.2.

Electrolytic Copper.—Blum and Rawdon, of the Bureau of Standards, presented a paper at the forty-third meeting of the American Electrochemical Society in May, 1923, in which they reported some experiments as to the effect of a rolled or cast copper base upon the copper electrolytically deposited thereon. Statements have been made that the structure of the surface has no influence on the deposit, but Blum and Rawdon found that if the base has been cleaned with nitric acid an influence is exerted, but if cleaned with alkali no effect is produced.

German Chemical Industry Developments.—We are informed by Messrs. Ronsheim and Moore, of 11a, Wormwood Street, London, E.C.2, general agents in the U.K. and Colonies for the Saccharin-Fabrik, A.G., that the Upper Silesian Coke Works and Chemical Works and the Saccharin-Fabrik, A.G., have agreed to work in conjunction without either firm in any way forfeiting its independent character. The arrangement for the furtherance of the companies' joint interests will be effected by an exchange of shares and the nomination of members of the Board of one company to sit on the Board of the other and *vice versa*.

Wood Distillation in Mysore.—A charcoal blast-furnace with a capacity of 60 tons per day, combined with a wood-distillation plant, has, states a correspondent to *The Times Trade Supplement*, been erected and put into operation at Birur, on the Bhadra River, Mysore, India. The plant, which was designed by Messrs. Perrin-Marshall, of New York, and erected by the Tata Iron and Steel Company, is owned by the Mysore State Government. The distillation plant has been laid down to deal with 240 tons of wood daily, with provision for increasing the capacity to 400 tons per day. The crude pyroligneous acid is separated from the tar, which is used as a wood preservative, and worked up into crude acetate of lime and marketable methyl alcohol. The Government are desirous of interesting private capital in the provision of plant for the manufacture of acetic acid from the lime acetate.

German Dyestuffs Manufacturer's Profits.—The reports of all the large German dyestuff makers, comprising the I.G., have now been issued. Considerably increased profits, in paper marks, are shown, and all the companies are paying 300 per cent., as against 30 per cent. last year. The reports mention that the dividend is less than one gold mark (80 gold pfennigs) per 1,000 mark share. Very few particulars regarding the course of trade are given by any of the concerns. The A. G. für Anilinfabrikation, Berlin, states that the new works for the manufacture of artificial silk are now producing. It is also said that the company intends to build two large new factories for the manufacture of dyestuffs, one near Bitterfeld and one which will specialise in the production of azo colours at Greppin. The Chemische Fabrik Griesheim-Elektron, Frankfort-on-Main, states that the works were well employed last year. The A. G. Farbwerk Mülheim vorm A. Leonhardt and Co., states that sales last year were good, particularly in Germany.

IMPORTS OF CHEMICALS INTO INDIA.

NEW TARIFF VALUATION.

REVISED schedules of tariff valuations have been issued by the Department of Commerce of the Government of India for the purpose of levying Customs duties in British India during the period ending December next. The new schedule took effect on April 1 last.

Articles.	Per	Tariff Valuation	Duty.
		Rs. a.

SOUTH WALES NOTES.

[Specially Contributed.]

The tone of the tinplate industry is rather weaker, orders being of small dimensions and business for forward delivery scarce. Although the majority of the works are in fair activity at the present, contracts over the current quarter are at a low ebb. With slight reductions in prices, the galvanised sheet trade has improved, and the demand seems to be expanding. The patent fuel trade is steadily improving, though the pitch position hinders rapid development. Home supplies of this commodity are scarce and quotations are again soaring. Fortunately most of the briquette manufacturers have plentiful supplies of foreign pitch, which places them in rather an independent position, while the supplies of small coals are abundant, with indications of lower prices. Fresh orders have been received for patent fuel from Brazil, Spain, and Denmark, and the outlook is generally much better. Cokes are in better supply, the outputs being much heavier, especially of the furnace qualities. All the ovens are working satisfactorily, and the supply of products is on the increase. So far as the latter are concerned there is little or no difficulty in finding ready markets for the residuals, with the exception of sulphate of ammonia, which at present is rather dull.

Among the exports were—From Newport 58 tons sulphate of iron to Antwerp, 70 tons ammonium nitrate and 8 tons zinc ashes to Hamburg, 10 tons sulphate of iron to L'Orient. The imports for the week to Cardiff included 63cwt. red powdered arsenic from Antwerp, 209 tons burnt ore from Dublin; into Swansea, 197cwt. barytes from Hamburg, a cargo of copper ore from Lisbon, 266 bags precipitate of copper from Pomeron, 51 tons spelter from Copenhagen; to Newport, 200 tons crude zinc from Hamburg, 2,580 tons iron pyrites from Huelva, 105 tons calcium carbide from Antwerp; to Port Talbot, 2,600 tons manganese ore from Abuzemiuma.

FERTILISER NEWS.

Nitrate of Soda.—The preliminary statistics, as issued by the leading brokers, relating to the half year which has just ended, were naturally based on the estimated shipments and port deliveries for the month of June, seeing that the half-yearly reports were issued immediately at its close. Subsequent cabled figures, however, rather modify the large figure of 165,000 tons exported from Chile during the month, and the shipments are now given at 143,000 tons—a difference of over 15 per cent. With production at 153,000 tons, stocks on the West Coast, as was anticipated in this column a fortnight ago, reach over a million tons. The European quota was more or less correctly forecasted, but the American figure, and the quantity destined for "other countries" were overestimated by 11,000 tons each! Total exportation for June, 1914, reached 183,000 tons. From America it is reported that the situation is very quiet. The increasing price scale is, of course, in operation there, but it is stated that despite the fact of plentiful money the spot market is showing little business. As the quotation for second-hand spot material is at a much lower figure, the future is rather cloudy. Compound fertiliser manufacturers do not appear to be buying, in spite of the fact that later prices are bound to be higher. Total sales so far effected by the Producers' Association for delivery after July 1 amount to about 890,000 tons, of which 3,000 tons is for delivery next spring. This quantity is more than covered by the existing stocks on the West Coast. Production, which is gradually on the increase, should provide a further 950,000 to 1,000,000 tons, even at the 60 per cent. of capacity output now obtaining. The first half of next year should see yet another million tons, making in all, an available quantity of 3 million tons. Orders are at present falling off, and it is not likely that heavy buying will set in, if at all, until nearer the consuming season. In the meantime, supplies of nitrogen from other sources, including the "despised" synthetic plants, are increasing, and selling at a lower unit price. Failing the recurrence of the favourable external market conditions, it seems as if the price—or the consumption—of nitrate will drop during the coming season.

Sulphate of Ammonia.—The reduced prices, announced in this column last week, have attracted more attention to the fertiliser. The value of the neutral quality, containing 25¾% of ammonia, works out at 13s. 11d. per unit of nitrogen. This compares very favourably with 16s. 7d. per unit for nitrate of soda when the latter is £12. 17s. per ton. The export trade continues of fair dimensions, and the general outlook is still very favourable. Recent advices from the United States point to the fact that the output, large though it is expected to be, will be mostly absorbed by the domestic demand, which gives indications of being larger than ever during the coming fertiliser year. Some second-hand material has been exported from the States to the West Indies and Cuba, but the volume of British trade in that quarter has never been considerable. Prices are on the high side and likely to remain so in view of the good demand. The spot price, f.o.b. works is $3.20. to $3.25., with small resale lots at $3.10. per 100lb. For export, in double-bags, f.a.s. New York, $3.55. to $3.60. is quoted, which is equivalent to about £17. 14s. per ton at current exchange rates. It is clear that there is a market therefore, for all the British sulphate that can be produced. It is the high margin of profit thus afforded to exporters of British sulphate which has permitted the considerable reduction of home prices. Some dissatisfaction has been expressed anent the rigid clause, insisted on by the Federation, which deals with the ultimate exportation of sulphate originally sold for home requirements at the scheduled price. In view of the looseness of commercial morality among a certain type of merchant, many of whom have figured in the courts during the past two or three years, a wholesome tightening-up, even to the extent shown, is definitely needed, and the very fact of the prominence given to the clause by the Federation points to its necessity.

General Notes.—On account of many blast furnaces in the Ruhr district of Germany having become idle, production of basic slag in Switzerland has been greatly curtailed, and its price has materially advanced, according to consular advice to the U.S. Department of Commerce. Authentic reports state that production is being reduced daily and the lack of new stocks will be seriously felt as soon as the demand in Switzerland becomes strongest, which will be the case shortly.

The Minister of Agriculture has appointed a small Departmental Committee to inquire into the operation of the Fertilisers and Feeding Stuffs Act, and to advise whether, and if so, what amendments are necessary to render the execution of the Act more economical and effective. The Committee consists of Lord Clinton (Chairman), Mr. E. Richards Bolton, Mr. E. G. Haygarth Brown, Dr. Charles Crowther, Mr. Thomas Kyle, Mr. Brian S. Miller, Mr. George Stubbs, Dr. J. F. T. Osher, Dr. J. A. Voelcker. Mr. H. J. Johns, of the Ministry of Agriculture and Fisheries, 10, Whitehall Place, S.W., has been appointed secretary.

In April, for the first time this year, the exports of fertilisers and fertiliser materials from the United States exceeded that of the corresponding month of 1922, having totalled $2,256,139. (98,236 tons) as compared with $1,666,956 (87,161 tons) in April, 1922. Heavier shipments of sulphate of ammonia and superphosphates were made, but smaller amounts of phosphate materials and prepared fertiliser mixtures were exported.

Sir Robert Harvey, speaking on Tuesday at the annual meeting of the Nitrate Railways Co., Ltd., said that during the year 1922 the railway had had no labour troubles, although in the ports and in Tarapaca generally there were, occasionally, signs of discontent among the workmen. "I regret to say, however," Sir Robert continued, "that at the present moment there is considerable labour unrest in the Port of Pisagua."

American Sulphur Exports.—A decrease of 14 per cent. was registered in the shipments of sulphur from the United States during April, 1923, as compared with April, 1922, exports having declined from $793,746 (53,501 tons) to $679,151 (42,034 tons). Canada was the best customer, with Germany a close second, and France, Spain, and Australia following in the order named.

PARLIAMENTARY NEWS.

Patents in the Irish Free State.

In the House of Commons, on Thursday, July 5, Lieut.-Colonel Buckley, replying to Col. Newman, said: The Government are in communication with the Irish Free State as to the course to be adopted by the latter as regards the granting of patents in future. In the meantime, so far as I am aware, the position of licensees under patents granted with validity throughout the United Kingdom has not been affected.

Reparation Dyestuffs.

Mr. Attlee, on Tuesday, June 10, asked the President of the Board of Trade whether he is aware that the British Dyestuffs Corporation, Limited, charge 10 per cent. commission on reparation dyestuffs, whereas, when the distribution was undertaken by the central importing agency, only 2½ per cent. was charged; and will he state for what reason this high rate of commission is permitted.

Sir P. Lloyd-Greame: I am not aware that the British Dyestuffs Corporation charge 10 per cent. commission on reparation dyestuffs and would refer to an answer which I gave on this matter on December 4 last to the effect that the Corporation receives a commission of 6½ per cent. on the actual turnover, plus a further 1 per cent. for guaranteeing accounts, and a grant which is limited in amount towards the charges which they incur relating to the importation of the dyestuffs. The central importing agency undertook the duty of distributing and distributing the dyestuffs for a commission of 3½ per cent., the rate to be adjusted if prices fell. But this charge proved to be inadequate, and was considerably increased with the approval of the Treasury by various allowances made to the central importing agency upon the final adjustment of their accounts.

Mr. Attlee: Is the President of the Board of Trade aware of the high prices charged for reparation dyestuffs by the British Dyestuffs Coroporation, Limited; that the price of diamine fast yellow F.F., a dye for which there is no satisfactory British substitute, has been raised from 4s. per pound to 7s. 6d. per pound and to 10s. per pound, although this dye could be imported from Germany for 4s. 6d. per pound?

Sir P. Lloyd-Greame: No complaint about the price of this dye has been received by the Board of Trade, but the arrangements as to the pricing of reparation dyestuffs are being reconsidered, and the price of this particular dye will come under review.

Mr. Attlee: Is it not a fact that these very high prices are put on in order to enable the Corporation to foist inferior substitutes on the colour-users?

Sir P. Lloyd-Greame: There is no truth in any of the many allegations in that short statement.

Mr. Collison: It is a question not only of price but of the inferior nature of the dyes as shown in the qualities of the manufactured article.

Sir P. Lloyd-Greame: I think not.

CORRESPONDENCE.

CEMENT FROM SPENT OIL SHALE.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—It may interest your readers to learn that a first experiment with spent shale from the Scottish Oilfields at the Building Research Board's experimental station has produced a puzzolanic hydraulic cement of a tensile strength at three months' age greater than that required for Portland cement by the B.E.S.A. standard specification. My attention was directed to this waste material by Dr. A. P. Laurie, of Edinburgh. Samples were obtained from the Research Association of the Shale Oil industry. The cement is of a pleasant light red colour, and is much harder than ordinary Portland cement.—Yours, etc.,

H. O. Weller,
Director of Building Research.

Department of Scientific and Industrial Research,
July 4, 1923.

GAZETTE NEWS.

MORTGAGES AND CHARGES.

Holders (London) Ltd., London, E.C., chemical merchants.—Registered June 22, (£1,000. debs. (filed under sec. 93 (3) of the Companies (Consolidation) Act, 1908), present issue £300.

Morris and Co. (Stockwith) Ltd., chemical manufacturers.—Registered June 22, £15,000. deb., to Westminster Bank, Ltd.

Vegetable Oils and Margarine, Ltd., London, E.C.—Registered June 25, £15,000. 2nd debs.

SATISFACTIONS.

Bleachers' Association Ltd., Manchester. — Satisfaction registered June 25, £65,000., balance of amount registered April 20, 1910.

Neuchatel Asphalt Co., Ltd., London, S.W.—Satisfaction registered, June 25, £2,000., registered July 5, 1920.

LIMITED COMPANIES. — Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions; Orders; and Official and Other Notices.

Anglo-Continental Oil Co., Ltd., London, E.C.—Resolved May 23, confirmed June 12 that the company be voluntarily wound up. V. C. Bianchi, 34, Nicholas-la., E.C., C.A. liqr.

Ineson Gibbs Oil and Chemical Co., Ltd., Birmingham.—R. L. Biggs ceased to act as receiver. June 6.

London Dye Manufacturing Co., Ltd., London, E.—W. G. Wilson, 37/39, King William Street, E.C. Appointed receiver June 23.

Schultze Gunpowder Co., Ltd.—Resolved June 7, confirmed June 25, that the company be voluntarily wound up. W. Morris and ano. lqrs.

DISSOLUTIONS OF PARTNERSHIP.

(*Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.*)

Tebbutt, Strange and Co. (Lionel Francis Tebbutt, Lionel Hastings Strange and Chas. Horace Ivinson), Imperial Buildings, New Bridge Street, E.C., manufacturing and research chemists and chemical and general manufacturers, merchants, traders, brokers, and agents. May 12. L. H. Strange continues. (June 29.)

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

Barends, H., 124, Warbreck Road, Blackpool; manufacturing chemist; £26. 1s. 4d. May 15.

Hall, Harry H., Sladen Dyeworks, Littleborough; dyer; £12. 7s. 6d. May 7.

London Hygienic Chemical Co. (1922) Ltd., 5, Wine Office Court, Fleet Street, E.C.; £11. 3s. 5d. April 21.

PUBLICATIONS RECEIVED.

Pneumatic Collection and Conveying.—Publication No. 1,093 of the Sturtevant Engineering Company, Ltd., 147, Queen Victoria Street, London, E.C. 4. An attractively produced booklet dealing exhaustively with the whole subject, and illustrating the well-known and well-tried machinery of the Sturtevant firm. Copies may be obtained by readers by application, mentioning the *Chemical Trade Journal and Chemical Engineer*, to the Publications Committee at 149, Queen Victoria Street.

Forge Plants and Forges. — Another publication of the Sturtevant Company dealing with the principles underlying successful smithy plants, the design of forges, the supply of adequate blast and the efficient removal of smoke and fumes from the smithy; together with details of Sturtevant forges and equipment. Copies may be obtained by readers as mentioned above.

REPORTS OF COMPANIES.

W. J. Bush and Co., Ltd.

The annual general meeting was held on Monday, in London, Mr. J. M. Bush (chairman and managing director) presiding. The Chairman, in moving the adoption of the report and accounts, said: The past year has shown no great revival in trade activity, and several of the continental markets have remained practically closed to us on account of depreciated currencies. The cold and wet summer also lessened the demand for many of our products. In spite of these adverse factors the figures present an agreeable comparison with those of the previous year. The improvement is due mainly to the fact that the depreciation in the value of our stocks which took place in 1921 was not continued into the period under review. Our subsidiary company in the United States, which, in common with the parent company, made a loss in 1921, became on a profit-earning basis again during the past year. Our Canadian company also made a moderate profit.

During the latter part of the year Dr. R. C. Farmer received an invitation from the Government to resume his position at the Woolwich Research Laboratory. He felt it his duty to accept, and resigned his directorship of this company. This we much regret, as during the comparatively short period he was with the company he had gained the esteem of all with whom he came into contact, and the company still continues to derive benefit from the improved methods which he introduced.

The motion, which was seconded by Sir G. Hayter Chubb, was carried unanimously.

Benzol and By-Products, Ltd.

Sir H. O. Bax-Ironside, presiding over the third ordinary general meeting held on Thursday (July 5) in London, said: It is anticipated that the ensuing period will show no loss. The actual loss due to the strikes and depression in the industry is reduced to £29,292. 18s. by writing back the amount of £8,000. out of the income-tax reserve and by £7,201. 0s. 9d. brought forward from the previous profit and loss account. The period covered was undoubtedly one of the worst in colliery history. It was even followed by several months of universal trade depression in our industry. As to the outlook, I may say that while an important long-term contract has been entered into having direct bearing upon our raw material supplies, we are negotiating a twenty-years' contract to light another, and more important, adjacent town with our coke-oven gas. You are aware that we already have a fifteen-years' contract to light the neighbouring town of Ossett. Our profits in the past have been chiefly derived from our coke-ovens and by-product works. It is proposed to extend our present battery of coke-ovens and to add requisite by-product plant. It is intended to strengthen our board by the appointment of a well-known Yorkshire colliery director as local director, he being chosen by the representatives of the largest collective body of preference shareholders,

The report and accounts were adopted.

Welsbach Light Co., Ltd.

The report for the year ended March 31, states that the question of reimbursement of E.P.D. by the revenue authorities is still unsettled, pending which, income-tax and corporation tax for the past two years have not been paid. Including profit on realisation of investments and debenture stock redemption (together £18,093.), the net profit for the year was £26,397., and adding £18,412. brought forward, there is a total of £44,810. It is proposed to pay a dividend of 5 per cent., less tax, and a bonus of 2½ per cent., less tax. The transfer to general reserve is also proposed of unappropriated discounts on debenture stock redeemed, amounting to £7,520., leaving £17,945. to be carried forward, subject to taxation settlement. The net profit for the preceding year was £9,726., the dividend was the same, but no bonus was paid.

British Cyanides Co., Ltd.

The profit for the year ended April 30 was £17,204., which, with the amount brought forward, makes a total of £17,697. This compares with a total profit last year, including the amount brought in, of £3,342. After the payment of the dividends on the preference shares for the year, there remains a sum of £14,847., as compared with £492. for 1922, which is carried forward. The report states that the profits realised were almost entirely earned during the last few months of the period under review. The balance-sheet shows, apart from loans to subsidiary companies, that stocks of materials, etc., amount to £52,267.; sundry debtors, £30,421., as against creditors, £27,379.; cash in hand and at bankers, £9,850.; as against £4,880. last year; whilst the bankers' overdraft has been reduced from £47,402. to £30,001.

Amalgamated Zinc (De Bavays), Co., Ltd.

Report for the half-year states that the balance of the appropriation account at June 30, 1922—viz., £25,000., was absorbed by the payment of the thirty-first dividend of 1s. per share. During the period under review the working account showed a profit of £38,920., after transferring £6,965. to reserve for depreciation. Taking into consideration the profit and loss debits, and after adding the amount of dividends received from shares in other companies, revenue from interest, discounts, exchanges and rents, the profit for the half-year transferred to appropriation account amounted to £39,078. Since the close of the half-year the thirty-second dividend has been declared, and will absorb £25,000. of the above-mentioned profit, leaving a balance of £14,078. to carry forward.

Mond Nickel Co., Ltd.

The report for the year to April 30 last, states that the balance-sheet shows a balance to the credit of profit and loss account of £330,268., which it is proposed to deal with as follows:—Interim dividend on the preference capital at 7 per cent. per annum paid March 3, less tax, £87,500.; dividend now to be paid on the preference capital at 7 per cent. per annum, £87,500.; interim dividend on ordinary capital of 6d. per share, paid March 3, free of tax, £22,500.; dividend now to be paid on ordinary capital of 1s. 6d. per share, free of tax, £67,500.; balance to be carried forward, £65,268. The demand for nickel improved during the year, and sales have been satisfactory. As a result, production has been increased.

Ebbw Vale Steel, Iron, and Coal Co., Ltd.

Accounts for the year to March 31 last show that the gross profit amounted to £426,117., making with balance brought in a total of £442,575. Legal and general expenses absorb £10,041., and interest on debentures and loans £363,402., leaving £69,131. to carry forward. The directors are unable to recommend a dividend on the 7 per cent. cumulative preference shares or on the ordinary shares of the company for the year.

DIVIDENDS.

Boots Pure Drug Co., Ltd.—The directors have declared an interim dividend of 9 p.c. (less tax) on the new ordinary shares with respect to the quarter ended June 30.

Canadian Explosives Co., Ltd.—Dividend of 1¾ per cent. for the quarter to June, 30, 1923, on the 7 per cent. cumulative preferred shares.

Canada Cement Co., Ltd.—Dividend of 1½ per cent., less tax, on common stock for quarter.

Kinta Tin Co., Ltd.—During 1922, after allowing £4,200. for depreciation, the net profit was £18,491. (against £15,973.). Dividends have been paid during the year amounting to 10 per cent. (against 5 per cent.), leaving a balance of £6,491., which has been written off investments account, reducing it to £5,297.

Broughton Copper Co., Ltd.—Report for past year states that the profit, after providing for taxation, amounted to £51,594., plus £3,061. brought in, making £54,655. Final dividend of 10 per cent. (actual).

Amalgamated Photographic Manufacturers, Ltd.—Accounts for 1922 show net profit £25,049., including £10,507. in respect of adjustment of taxation reserves. Preference dividends up to June, 1921, absorb £14,047., leaving £11,002. to be carried forward.

THE PATENT LIST.

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Separating Gases and Vapours. Plauson's (Parent Co.), Ltd., London. H. Plauson, Hamburg, Germany. British Patent, **197,353,** of 1922.

Vapours or gases are separated by selective passage through a porus diaphragm in an apparatus in which a difference of electric potential (about 20-100 volts) is maintained between the diaphragm and the vapours or gases by applying an electric charge either to the diaphragm or to the gases. The diaphragm may have fairly large pores and may be formed of loose-powdered material such as sand, glass, carbon, graphite, carborundum, metal, china clay, silicic acid, cement, chalk, gypsum, feldspar, etc., or of these materials treated to form a rigid diaphragm by addition of a binding agent, or by ignition, chemical decomposition, etc., or of superimposed slotted or corrugated metal plates or wire netting between which porous material may be placed. Vapours generated by heating a liquid in the lower part 2, Fig. 1, of a still rise into contact with a porous diaphragm 3 clamped by insulated connections 5, 6 between the lower part 2 and the upper part 1. A perforated electrode 7 is arranged below the diaphragm and connected to the part 2. Electrical connections 15, 16 are made with the parts 1, 2. A diaphragm in the form of a number of connected porous cylinders and an electrode having arms projecting into the cylinders, may be used.

FIG 1.

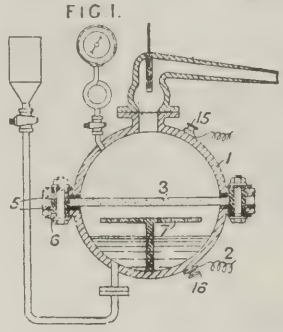

FIG 14.

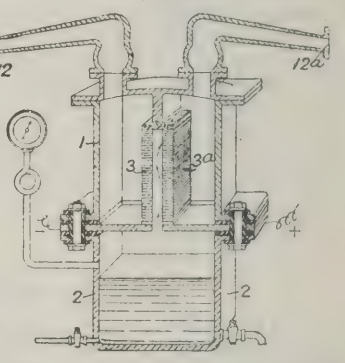


Two diaphragms may be placed in series, and may be formed of loose material resting on perforated plates in electrical connection with the parts of the still. The diaphragm may be cleaned during use by removing impurities which settle on its surface, as, for example, during the distillation of oils containing wax, naphthalene, anthracene, asphalt, etc., either by forming the diaphragm as a hollow rotary cylinder, against which a scraping knife or rotary cleaning brush is held, or as a hollow fixed cylinder containing a rotating cleaning-worm. The vapours generated in the still 2, Fig. 14, pass into the space between two diaphragms 3, 3*a*, one of which is charged positively and the other negatively, and the vapours which pass through each diaphragm are removed by separate outlets 12, 12*a*. The apparatus may be used for the distillation of petroleum, and for the separation by distillation of two liquids having about the same boiling-points but of different polarities. According to the Provisional Specification, the diaphragm may also be made of blood-charcoal or kieselguhr.

Iron Oxide in Glass Manufacture. Chance Bros. and Co., Ltd. and A. L. Forster, Smethwick, Staffordshire. British Patent, **197,500,** of 1922.

Relates to glass of the kind in which iron oxide is combined in the ferrous state to enable the glass to act as a good absorber of thermal radiation. According to the invention, the proportion of iron oxide is such that the amount of ferrous oxide per unit area of the glass will give the desired absorption and transmission of thermal and luminous radiations. For example, hammer scale or iron oxalate is added in such quantity that the finished glass sheet contains about .01 of a gramme of ferrous oxide per square centimetre of surface. It is found that with such a glass, the ratio of luminous radiation transmitted to thermal radiation absorbed is a maximum, and the glass is suitable for window and roofing purposes in hot countries.

Organic-mercury Compounds. M. E. Wolvekamp, Oakland, California, U.S.A. British Patent, **196,431,** of 1922.

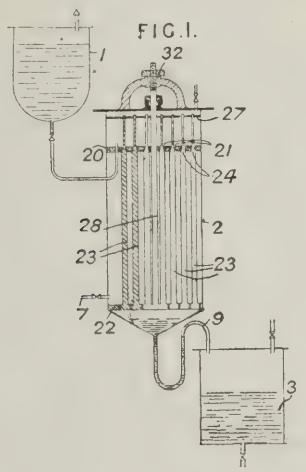
Mercury derivatives of aurintricarboxylic acid and alkali salts thereof are obtained by heating with mercury compounds a solution of an alkali salt of the acid, or a suspension of the acid in a solution of sodium chloride. The products, which may contain one, two, or three atoms of mercury in the molecule, are substitutes for mercury salicylate; the free

acids are insoluble in water, but soluble in sodium chloride solution. According to examples, products containing sodium chloride are prepared by boiling aurintricarboxylic acid with sodium bicarbonate, mercuric chloride, and water, filtering, and evaporating; products not containing sodium chloride are obtained by replacing the mercuric chloride by mercuric oxide, the mercuric aurintricarboxylates being precipitated by acidifying with sulphuric acid.

Treating Liquids with Gases. A. H. Shaw, and Peachey Process Co., Ltd., London. British Patent, **197,368,** of 1922.

In the impregnation of liquids or solutions with soluble gases, the liquid descends in fine streams in a closed vessel into which the gas is introduced, the flow of liquid being adjusted in such a manner that, by this adjustment, the capacity of the closed vessel is appreciably increased or decreased as the flow of liquid is increased or decreased. The apparatus comprises a closed vessel 2 provided with a plate 20 having apertures 21, which are controlled by conical shoulders 24 on a series of rods 23 secured to or formed integrally with a movable false bottom 22, which

FIG. I.



may be raised or lowered by a central spindle 28 and screwed nut 32. The false bottom is perforated to allow the impregnated liquid to pass, by a pipe 9, to a collecting vessel 3. The liquid to be treated is introduced, from a supply vessel 1, to the closed vessel above the apertured plate 20, over which is fitted a second apertured plate 27, which guides the upper ends of the rods 23. Gas enters the vessel 2, through a pipe 7, above the highest position of the false bottom. The apparatus may be used for the vulcanisation of caoutchouc according to Specification 129,826, the rubber solution or benzine being contained in the vessel 1, and sulphur dioxide and hydrogen sulphide being admitted to the closed vessel 2 separately through pipes such as 7; or, alternatively the solution or liquid may be treated with each of the gases in a separate vessel.

Decolourising Liquids. A. C. Cumming and Klarit, Ltd., Liverpool. British Patent, **196,002,** of 1921.

"Carbon-black" substantially free from oil is used for decolourising fats, oils, sugar solutions, and other liquids. Solid adsorbents such as kieselguhr or china clay may be mixed with it. The "carbon-black" may be freed from oil by heating to redness out of contact with hydrocarbons. Specification 25571/99 is referred to.

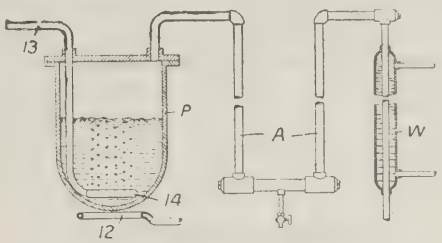
Desulphurising Oils. A. C. Nesfield, London. British Patent, **196,680,** of 1922.

Minerals oils are desulphurised by impregnating them with hydrochloric acid gas and air, or a mixture of hydrochloric acid gas, hydrogen, and air, washing the treated oil with caustic soda or lime water, and filtering by centrifuge or otherwise to remove the sulphur, etc. The oil may be treated in gaseous form, or may be exposed to the gases as a film or spray, or the gases may be bubbled through it. Crude shale oil or spirit may be distilled into two fractions terminating at about 392° F. and 750° F., each fraction being separately treated. To obtain white spirit, the oils, after washing with alkali, may be further washed with 2 per cent. of sulphuric acid; if emulsification occurs, the oil is washed with sodium chloride solution.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Benzaldehyde and Benzoic Acid. Carbide and Carbon Chemicals Corporation, New York, U.S.A. (Assignees of H. R. Curme, New York, U.S.A.) British Patent, **197,319.** Convention date, May 4, 1922.

Benzaldehyde and benzoic acid are obtained by bringing free oxygen into contact with dibenzyl at elevated temperatures. The dibenzyl may be employed in the liquid or vapour phase; oxygen or oxygen-containing gases, such as air, may be used; and the oxidation may take place at normal or increased pressure. In the form of apparatus



shown, P is a covered vessel containing liquid dibenzyl, which is heated by a burner 12 and into which the oxygen-containing gas is introduced through a pipe 13 and perforated ring 14; the bulk of the reaction product is condensed in the air condenser A, and the remainder in the water condenser W. A scrubber may be employed in replacement of or in addition to the condenser W. The dibenzyl may be fed continuously into the reaction vessel, whilst a series of reaction vessels may be employed in cascade.

Coating Aluminium. Aluminium Company of America, Pittsburgh, U.S.A.—(Assignees of A. Pacz, East Cleveland, Ohio, U.S.A. British Patent, **197,306.** Convention date, May 8, 1922.

An oxide coating is produced on aluminium or aluminium alloys by treatment with ammonia solution, preferably nearly at boiling point, the solution containing, for example, one volume of concentrated aqua ammonia to nine of water. Alloys with nickel, tungsten, silver, iron, copper, zinc and copper, in specified proportions, and with other metals and silicon in unspecified proportions are referred to as producing a wide range of characteristic colourings, or specified amounts of salts of such metals as will produce the desired colour are dissolved in the bath. The coating on pure aluminium may be darkened by hanging a metallic plate, *e.g.*, of silver or nickel, in the bath, silver, in the former case, being deposited on the aluminium. The coating is electrically insulating, and serves as a basis for painting or electro-deposition.

Alcohol and Ammonium-Sulphate Manufacture. Compagnie de Béthune, Pas-de-Calais, France. British Patent, **197,315.** Convention date, May 4, 1922.

Ethyl alcohol is obtained from sulphovinic acid by treatment with a reagent which fixes the sulphuric acid content with evolution of heat, thereby determining the distillation of the alcohol without the application of external heat. Ammonia, either as gas or in the form of solution, is described as the reagent, in which case ammonium sulphate is obtained as a by-product. According to the example, a stream of ammonia gas is conducted into sulphovinic acid or sulphuric acid containing sulphovinic acid; the alcohol distils off to a dephlegmator and is condensed; ammonium sulphate settles out or remains dissolved in the ammonia-saturation vessel. The operation may be carried out at normal or reduced pressure

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

The efforts to arrive at a settlement of the dispute at the Whitehaven Collieries had not in mid-week proved successful, and as the pits are still idle, the production is not sufficient to meet requirements. The import of smalls has ceased, and the Whitehaven coking plant has only ten ovens in operation. The other ovens are all working, but not at full pressure. So far the entire make continues to be absorbed by the furnaces that are smelting ordinary iron in West Cumberland, but the Newcastle pig-iron trade is so poor that it would occasion no surprise were one or two furnaces to be damped down in this district as well as in the Furness area. The hopes of any immediate recovery in the iron trade on the North-West Coast are of the slenderest. Newcastle pig-iron has fallen now to £5. 18s. 6d. per ton delivered at Glasgow and Sheffield, but even that figure does not tempt any flow of business other than that of a hand-to-mouth character. The prospects have not been poorer for seven or eight months past, and no one can say that the depression will be of short duration. The coal trade has not yet been adversely affected, any diminution in the needs of local landsale and industrial purposes having been compensated for by the willingness of Irish consumers to take all the coal they can get hold of. Prices are fully maintained. By-products and chemical products are a fairly good trade. East Coast coke supplies this week are short by 7,200 tons.

NEW COMPANIES.

New Motor Spirit Co., Ltd. Capital, £50,000., in 30,000 8 per cent. cumulative participating preference shares of £1. and 200,000 ordinary of 2s. Office: Finsbury House, New Blomfield Street, E.C.2.

A. G. Collins and Brother, Ltd.—Private company. Capital, £5,000. Oil refiners and blenders, soap, grease, tallow and candle manufacturers, etc. Solicitor: A. C. Hooper, Post Office Chambers, Bute Docks, Cardiff.

Bideford Storage, Ltd.—Private company. Capital £1,000. Manufacturers and dealers in fertilisers, seed crushers, and warehousemen, etc., Solicitors: Linklaters and Paines, 2, Bond Court, Walbrook, E.C.

Carlton Laboratories, Ltd.—Private company. Capital £5,000. Office: 6, Norwich Road, Triangle, Bournemouth.

Doughty-Richardson Fertilisers, Ltd.—Private company. Capital £50,000. Solicitors: Toynbee, Larken, Mason and Co., 7, Bank Street, Lincoln.

Hardy, Brown and Co., Ltd.—Private company. Capital £500. Manufacturers of and wholesale and retail dealers in paints, colours, etc. Office: 3, Charles Street, West Hartlepool.

London Lead Oxide Co., Ltd.—Private company. Capital £25,000. Office: 107, Bishopsgate, E.C.

Mann and Bishop, Ltd.—Private company. Capital £25,000. Dealers in chemicals, dyestuffs, fertilisers, etc. Office: 36-7, Mincing Lane, E.C.

Thos. S. Sutton and Sons, Ltd. Private company. Capital £10,000., £1. shares (9,000 vendors' and 1,000 ordinary). Tin and solder and by-products manufacturers and merchants. T. S. Sutton is permanent managing director. Office: Mill-Lands Works, Neath, Glam.

Paisley Oil and Chemical Co., Ltd.—Private company. Capital £5,000., £1. shares (1,500 preference). Office: Minerva Works, Linwood Road, Paisley.

THIRTY-FIVE YEARS AGO.

(From the "Chemical Trade Journal," July 14, 1888.)

Patent Office in 1887.—The fifth report of the Comptroller-General of Patents, Designs, and Trade Marks for the year 1887 was published recently as a Parliamentary paper. The total number of applications for patents in 1887 was 18,051, for designs 26,043, and for trade marks 10,586. These numbers are considerably in advance of the average of the three previous years. It appears from a table given that the proportion of applications made by persons resident in the United Kingdom was 76 per cent.—a total which varies but slightly from the average. Of the applications made during the year 53 per cent. were proceeded with. There were twenty-six applications made under the provisions of the International Convention, which was joined during the year by the Government of the United States. With regard to trade marks, 4,916 marks were advertised and 4,740 were registered. The total receipts for the year amounted to £124,279., of which £105,599. was for patent fees, £4,855. for designs, and £8,463. for trade marks, while £5,360. was received from the sale of publications. The chief items of expenditure were £47,110. for salaries, £2,304. for pensions, £3,050 for stationery, and £22,300. for printing specifications, lithographing, drawings, and other such expenses. A balance of £42,702. was left at the end of the year.

MARKET REPORTS.

LONDON "OPEN MARKET" REPORT. Wednesday.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals.—Another week of very poor business is reported from all quarters. Prices, however, are keeping up to their former levels and there is no change of material importance to comment upon. **Acetic Acid,** 80% technical, £47.; 80% pure, about £50.; 98% glacial, £60. in casks and about £75. in glass demi-johns, ex wharf, London; quoted prices for the little material available on spot seem very firm; business has been very limited. **Acetone,** British Government specification, about £120. per ton; with very little material about this price is fully maintained; some inquiry on the market. **Arsenic,** Cornish white powdered, about £71. per ton; there is perhaps a slightly easier feeling in this market. **Alum,** lump, in casks, about £10. 10s. per ton, dealers offering Continental material at about these figures find business very slow. **Anhydrous Ammonia,** 99.95, 1s. 5d. to 1s. 5½d. per lb.; importers are offering at about these rates. **Barium Chloride,** 98—100%, £15. to £15. 5s. per ton; last week's easier prices are being quoted with little business about. **Bleaching Powder,** 35—37%, £10. to £10. 10s. per ton; Continental material is offering at about these prices, but the demand is small. **Borax,** commercial, granulated, £26. 10s.; crystals £27., powdered £28, extra fine £29.; B.P., crystals £31., powdered £32., extra fine £33. per ton, for home trade only, in free 2cwt. bags, carriage paid to destination. British makers' prices show no change on the week. Importers are offering under similar conditions, commercial granulated at £25. 10s., and powdered £27. per ton. **Borax Glass,** lump, £74., powdered £75. per ton, in tin lined cases; British makers' prices are unchanged at these rates for home trade only, packages free, carriage paid to destination. **Boric Acid,** commercial, crystals, £50., powdered, £52.; B.P., crystals £56., powdered £60.; extra fine £62.; in bags, free, carriage paid to destination; British makers are selling for home trade only at these prices; dealers are competing at about level figures. **Cream of Tartar,** 99—100%, 92s. to 94s. per cwt., less 2½%; a fair volume of business continues, with quoted prices steady. **Citric Acid,** B.P., crystals, about 1s. 9d. to 1s. 9½d. per lb.; there has been a little better inquiry of late and the market seems quite steady. **Epsom Salts,** commercial quality, about £5. per ton, in bags; there is still but very little business doing in this product. **Formaldehyde,** 40%, about £96. per ton, nominal; there is little if any business passing in this product, and the market is likely to remain idle until the referee's decision is published. **Glauber's Salt,** commercial quality, about £3. 15s. to £4.

per ton, in bags; scarcely any inquiry on the market—quoted rates unaltered. **Lead Acetate,** brown, about £42.; white crystals, about £43. to £43. 10s. per ton; quoted rates are now quite steady, but business has been slower. **Litharge,** pure flake, British, about £37. per ton; dealers are offering Continental material at about £35. 10s. per ton. **Lithopone,** 30% Continental red seal, £22. 10s. per ton; this market is very steady and a fair volume of business continues; supplies are still rather restricted. **Ammonium Chloride,** grey galvanising, about £30. 10s.; spot stocks are still offering at about this price, but business is slow. **Nickel Sulphate,** home trade, single and double salts, £38. delivered; export, single and double salts, £38. per ton, f.o.b.; British makers' prices show no change on the week. **Oxalic Acid,** about 6d. to 6¼d. per lb.; this market remains a dull feature and prices are none too steady. **Bichromate of Potash,** about 6d. per lb.; little in the way of good business has come to dealers—quoted rates are unchanged. **Carbonate of Potash,** 90—92%, about £28. 10s. to £29.; 96—98%, about £32. per ton; the market seems a shade easier again this week and is still lacking good business. **Chlorate of Potash,** crystals and granular, about 3d. per lb.; quoted steadily, but not much doing. **Caustic Potash,** 88—92%, about £33. per ton; dealers offering at these rates, which seem unsteady, are doing very little business. **Permanganate of Potash,** commercial quality, about 9¾d. to 10d. per lb.; conditions in this market are dull, and prices seem to be cheapening. **Prussiate of Potash,** yellow, about 1s. 3¼d. per lb.; merchants are quoting at slightly easier rates again this week—some little business has been done. **Sulphate of Potash,** 90%, £11. 10s. per ton, ex ship; quoted rates show no change on the week. **Mercury,** about £11. per bottle of 75-76lb., net; this market has been rather quiet this week, but prices seem quite steady. **Red Lead,** imported, about £35. 10s. per ton, c.i.f. London; dealers are offering at about this rate, with some little business about. **Salammoniac,** dog-tooth crystals, £49.; medium, about £43.; fine white crystals, about £27. to £28. per ton; spot supplies are available—prices are unchanged, with the market dull. **Saltcake,** ground and unground, home trade, about £5. per ton; delivered; export, about £5. 10s. per ton, f.o.b.; makers are said to be sold out to end of the year. **Acetate of Soda,** about £25. per ton; dealers are quoting for forward delivery at about this level. **Soda Ash,** 58% light alkali, £7. 12s. 6d. per ton, in bags, carriage paid to destination; British makers are quoting at this level for home trade only; their prices for export vary as to destination. **Soda Crystals,** £5. 5s. per ton, in bags, carriage paid to destination; British makers quote at about this rate for home trade only and dealers are selling at very competitive prices. **Caustic Soda,** 70—72%, £18. 10s.; 76—77%, £20. 10s. per ton, ex wharf, shipping port; dealers have reduced their quoted rates by £1. per ton, but still find business slow. British makers quote for home trade only from £19. to £21. 10s. per ton, in drums, carriage paid; prices for export vary as to destination. **Bicarbonate of Soda,** £10. 10s. per ton, in bags, carriage paid to destination; British makers' prices given; dealers are offering at competitive rates. **Chlorate of Soda,** crystals and granular, 2¾d. per lb.; dealers are doing but little—prices are fairly steady. **Cyanide of Soda,** 98—100%, 8½d. to 9d. per lb. for export; home trade, 10½d. to 11d. per lb.; British makers quoting at about these prices. **Nitrate of Soda,** 96%, about £13. 7s. 6d. per ton, f.o.r. Liverpool; there is no change to record. **Nitrite of Soda,** 100%, about £27. per ton; the market keeps steady at this unchanged rate. **Prussiate of Soda,** about 7d. per lb.; the tone here is not at all good, and business has been very poor. **Hyposulphite of Soda,** pea crystals, about £15. per ton, in 1cwt. kegs; commercial quality, about £10. 10s. per ton, in casks; prices are a little easier this week—some moderate business has been done. **Sodium Sulphide,** 60—62% solid, £14. to £14. 10s. per ton; ditto, broken, about £15. to £15. 10s. per ton, in drums; 60—65 concentrated, in casks, about £15. per ton; dealers are offering Continental material at about these prices, with not much business about. **Sulphate of Copper,** about £26. to £26. 5s. per ton, for home and export; British makers quoting at about these rates, delivered and f.o.b. **Tin Crystals,** 1s. 4d. per lb.; quoted rates unaltered—market steady. **White Lead,** imported, about £43. to £44. per ton; dealers prices are well maintained and some limited orders have been booked. **Zinc Oxide,** B.P., about £52.; white seal, about £44.; 99.5%, about £37. per ton, delivered in the United Kingdom; British makers continue to quote at these prices, with very little business doing.

Pharmaceutical Chemicals. Dealers continue to complain of the lack of good business, and again this week the little done has been mostly for small quantities. There is not much sign of any general break in prices, and the market continues fairly steady. **Acetanilid,** crystals and powder, about 1s. 6d. per lb.; the demand has been very slow—prices are easy. **Acetyl-salicylic Acid,** B.P., about 3s. 1d. per lb.; at this rate the market is fully maintained, and fair inquiry has been received. **Benzoic Acid,** B.P., about 2s. 6d. per lb.; this product is seldom asked for. **Diethylbarbituric Acid,** B.P. (barbitone), about 21s. per lb.; buyers are few—quoted rates are unchanged. **Salicylic Acid,** B.P., about 2s. 3d. per lb.; quotations seem to vary round about this figure. **Tannic Acid,** leviss, about 3s. 6d. per lb.; large quantities could be obtained for less—very little doing. **Amidopyrin,** about 14s. per lb.; this market seems steadier after last week's cheaper prices. **Ammonium Bromide,** about 7¾d. to 8¼d. per lb.; business remains slow and the market seems irregular on quotation and inclined to be weak. **Benzonaphthol,** about 5s. per lb.; no movement reported—quoted nominal. **Benzaldehyde 03,** about 3s. per lb.; the demand has been very limited—quoted unchanged. **Betanaphthol,** resublimed, about 1s. 10d. per lb.; at this rate the market is easy. **Calcium Lactate,** about 1s. 10d. to 2s. per lb.; some cheaper offers are being made for big lots. **Chloral Hydrate,** duty paid, 4s. to 4s. 3d. per lb.; some little inquiry has been dealt with at about these figures. **Creosote Carbonate,** about 8s. 6d. per lb.; the market rate is maintained, but there has been little doing. **Creosote,** B.P., about 2s. 2d. per lb.; things remain very quiet in this product. **Guaiacol Carbonate,** about 8s. 3d. per lb.; nominal; the market has been idle. **Hexamine,** about 4s. per lb.; business again has been restricted, and the market seems to be rather unsteady. **Hydroquinone,** 3s. 8d. to 3s. 9d. per lb.; the demand continues fairly good—prices are steady. **Methyl Salicylate,** about 2s. 6d. per lb.; matters remains very slow in this item, and prices are rather easier. **Methyl Sulphonal,** about 15s. per lb.; inquiry has been of the smallest—prices are unchanged. **Paraformaldehyde,** about 3s. 9d. per lb.; some limited business continues, with quoted rates level on the week. **Paraldehyde,** about 1s. 5d. per lb.; this rate is fully maintained, with fair inquiry about. **Phenacetin,** about 6s. 6d. per lb.; the market has been dull—quoted rates unchanged. **Phenazone,** about 7s. 6d. per lb.; the demand has slacked off—quoted rates so far unaltered. **Phenolphthalein,** about 6s. 3d. per lb.; there is very little offering on spot below this rate. **Piperazine,** about 3s. 6d. per oz., in kilo lots; spot material available, with very little demand. **Potassium Bromide,** B.P., crystals and granular, 6¾d. to 7½d. per lb.; offers are plentiful, with the demand showing no improvement. **Potassium Permanganate,** B.P., about 10¼d. to 10½d. per lb.; this market is not nearly so firm, and business has been slower. **Potassium Sulphoguaiacolate,** about 5s. 6d. per lb.; nominal—no business reported. **Salol,** about 2s. 9d. per lb.; this easier rate is being maintained on a dull market. **Sodium Benzoate,** about 2s. 6d. per lb.; things are very quiet—quotations are nominal. **Sodium Bromide,** crystals and granular, 7½d. to 8d. per lb.; quoted rates on spot are irregular, with the market well stocked and offers from the Continent plentiful. **Sodium Diethylbarbiturate,** about 18s. 6d. per lb.; nominal—market idle. **Sodium Salicylate,** powder, about 2s. 5d.; crystals, about 2s. 7d. per lb.; business during the past week has been quiet, and prices have rather an easier feeling. **Sulphonal,** about 15s. per lb.; nominal; the market remains stagnant. **Terpin Hydrate,** about 1s. 9d. per lb.; quoted rates from dealers are unchanged. **Thymol,** about 15s. per lb.; last week's easier rate is still quoted.

Coal-tar Products, Intermediates, Etc.—This market continues very depressed in the majority of products. Pitch is a shade firmer and in fair demand for forward delivery. Other products are quoted unchanged. **Aniline Oil,** about 9½d. per lb.; drums free; this market has been showing a little more activity of late. **Aniline Salt,** 9½d. per lb., casks free; the price quoted seem a little easier, business is slow. **Betanaphthol,** about 1s. 1d. per lb.; there has been some buying on a small scale of late. **Benzol,** 1s. 7d. per gallon, f.o.r. makers' works, in buyers' packages; some business for export has been done of late—home demand remains poor. **Toluol,** 2s. per gallon, f.o.r. makers' works, in buyers' packages; quoted rates are level on the week, with the market dull. **Xylol,** pure, 2s. 3d.; commercial, 1s. 6d. per gallon, drums extra; the demand remains slow—quoted rates are

level on the week. **Naphtha**, about 1s. 5d. per gallon, after last week's decline in values this market seems a little steadier, but is still very dull. **Solvent Naphtha**, 90—160, 1s. 5d. per gallon, drums extra; this price is still quoted, but the market is not at all steady. **Heavy Solvent Naphtha**, 90—190, 1s. 4d. per gallon, drums extra; business has again been dull—quoted rates unsteady. **Special Oil**, for Diesels and motors, 10d. per gallon, barrels free; there is no change in this market—business flat. **Burning Oil**, crude, No. 3, 8½d.; No. 2, 8d. per gallon, barrels free; there has been but little inquiry of late—quoted rates unchanged. **Creosote Oil**, 10d. per gallon, naked, f.o.b.; dealers are offering at level figures with business lacking. **Carbolic Acid**, crystals, about 1s. 2d. per lb.; last week's decline in price seems to have steadied the market, but there is still but little good business about. **Naphthalene**, about £20. per ton; the market has been neglected and prices are easier; crude, £7. to £13.; crystals, £21.; powder, £17. 10s.; balls, £24.; candles, £28.; tablets, £28. per ton, packages free. **Disinfectants**, 3s. 9d. per gallon, barrels free; the market has been idle. **Pyridine**, about 18s. per gallon; supplies on spot are still acutely short, and the price quoted is given as a nominal level. **Hexamethylene**, 4s. to 4s. 3d. per gallon; quoted rates from dealers are firm at these levels. **Pure Methyl Alcohol**, £100. per ton, ex wharf, London; the position remains firm—a fair inquiry about for the limited supplies available. **Pitch**, about 132s. 6d. per ton, spot London; about 145s. per ton is being quoted for forward delivery, and some good business is still being done in this direction.

LONDON METAL MARKET. Wednesday.

Copper: Standard brands, £65. 15s. to £65. 17s. 6d., cash; £66. 7s. 6d. to £66. 10s., three months; electrolytic, £72. 15s. to £73. 5s. **Tin**: Standard, £181. 2s. 6d. to £181. 5s., cash; £182. 2s. 6d to £182 5s., three months; Straits, £184. 5s.; English, £181. 12s. 6d. **Lead**, soft foreign, £24. 10s. prompt; English, £25. 15s.; chemical sheet, 33s. per cwt. for 2-ton lots, delivered. **Spelter**, prompt, £28. 12s. 6d.; hard, £24. **Antimony**, English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35 **Aluminium**, 98—99%, £115. to £120.; foreign, £110., c.i.f **Nickel**, £130., delivered; £125. to £130. for export, f.o.b **Mercury**, £10. 5s. to £10. 7s. 6d. **Bismuth**, 10s. **Platinum**, 500s. per oz. **Wolfram**, spot, 13s. per unit, c.i.f. United Kingdom or Continent. **Zinc Dust**, quotations are lower, as follows: Highest grade Englsh, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET. Wednesday.

Business all round still continues on the quiet side, and there is no improvement in demand for heavy chemicals; values on the whole continue unchanged. For alkali products, current quotations are as follows:—70% **Caustic Soda** £20. on rails, **Bicarbonate of Soda**, usual bags, £10. 10s. net per ton on rails. **Ammonia Alkali**, 58%, £7. 12s. 6d. per ton makers' works. **Bleaching Powder**, soft wood casks, quiet at £11. 7s. 6d. per ton, on rails. **Chlorates** continue in small request—**Potash** at 3d. per lb. and **Soda** 2¾d. **Bichromates** are unaltered at 5¾d. and 4½d. for **Potash** and **Soda** respectively. Roasted **Saltcake** continues in good demand for export, but for home trade there is little or no inquiry, and price is stationary at £4. 10s. to £4. 15s., carriage paid. There is only small inquiry for **Sulphate of Copper**, and quotations are nominal at £26. per ton f.o.b. Liverpool for usual brands. American imported **Sulphur** steady at £5. 5s. per ton on rails. **Phosphate and Commercial Hyposulphite of Soda** are only moving off slowly, and values show no improvement. **Nitrite of Soda** easier, at £26. 10s. net, ex store, basis 100%. Concentrated **Sodium Sulphide** weak at £14. 10s. to £15. per ton. White powdered Cornish **Arsenic** is offering for July delivery at £70. per ton on rails at works, but much lower prices are quoted for foreign supplies to come forward. Yellow **Prussiate of Potash** is weak at 1s. 3d. per lb.; **Soda** steady at 6¾d. to 7d. per lb., carriage paid. **Carbonate** and **Caustic Potash** have a higher tendency owing to scarcity of spot supplies. Grey and brown **Acetate of Lime** are unaltered in position or value. **Acetic Acid** and **Acetate of Soda** are firmly maintained at recent rates. In **Lead** Products, white **Acetate** is easier at £40. per ton, ex store; brown is firm and scarce at £42. to £43. per ton; **Nitrate** unchanged at £42. delivered. **Chloride of Barium** steady, at £15. per ton, ex store. There is fair inquiry for **Zinc, Tin,** and **Ammonia Salts,** and prices are fairly steady. **Green Copperas** is in good request, but prices are unchanged at 37s. 6d. to 40s. per ton, carriage paid in sellers waggons. **Oxalic Acid**, dull at 6d. to 6¼d. per lb. **Permanganate of Potash**, steady at 9¾d. to 10d. per lb.

SWANSEA MARKET REPORT. Wednesday.

Business in **Tinplates** was very indifferent, and few sales were notified on the basis of £1. 3s. 1½d. per standard box f.o.b. **Galvanised Sheets** in better demand, with easier prices at £18. 2s. 6d. per ton. **Copper** firmer at £64. 17s. 6d. per ton for prompt, and £65. 12s. 6d. three months. **Tin** easier, with prompt at £178. 12s. 6d. per ton, and three months £181. 7s. 6d. **Lead** dull at £23. 17s. 6d. per ton prompt, and £24. 2s. 6d. three months, for foreign; English, £25. **Spelter** dull, being, prompt, £27. 2s. 6d. per ton, and three months £28. 2s. 6d. **Zinc Sheets,** in fair request at £38. 2s. 6d. per ton. **Sulphate of Ammonia,** quiet, with home trade prices over quarter at £13. 12s. to £14. 15s. per ton. **Sulphate of Copper** dull, at £26. 7s. 6d. per ton, less 5%, in casks, f.o.b. **Nitrate of Soda** slow, at £13. 12s. 6d. per ton in bags. **Bone Meal** in little demand, with Indian prompt at £8. 12s. 6d. per ton ex ship. **Cottonseed Oil,** common edible, £2. 4s. 9d., and deodorised £2. 7s. 9d. per cwt. net. **Rape Oil** slow, with refined prompt at £2. 7s. 3d. per cwt. net, in barrels. **Oxalic Acid** very quiet at 6¼d. per lb. f.o.r. **Pitch** dearer, but scarcely any business done at £6. 12s. 6d. per ton ex ship for best qualities. **Sulphuric Acid** cheaper, with steady demand at £3. 7s. 6d. to £6. 17s. 6d. per ton f.o.r. **Arsenic** meets with poor sale, with white powdered round £70. 17s. 6d. per ton f.o.b. **Copperas,** £2. 2s. 6d. per ton, including delivery. **Palm Oil** rather quiet, Lagos, prompt, £35. 2s. 6d.; softs, prompt £34. 2s. 6d., and forward £34.; mediums £35. 2s. 6d., prompt and forward £35. 5s.; hards, £35. 2s. 6d. per ton. **Turpentine** easier, American prompt £4. 3s. 6d. per cwt. **Coals** quiet and steady; best Admiralty smokeless £1. 10s. to £1. 12s. 6d.; seconds, £1. 9s.; ordinaries £1. 8s.; Monmouthshire, black vein £1. 9s.; cargo smalls 17s. 6d., all per ton f.o.b. **Anthracite** very firm, with small supplies only available; best large, £2. 10s.; seconds, £2. 2s. 6d. Paris nuts, £3. 1s. 6d. per ton, all f.o.b. **Patent Fuel** quiet, from £1. 14s. to £1. 16s. per ton, f.o.b. **Cokes,** freely active; export, £2. 5s. per ton, f.o.b.; foundry, £2.; and furnace, £1. 10s. per ton f.o.r., at ovens.

LIVERPOOL CHEMICAL MARKET. Wednesday.

The demand for chemicals of the heavier kinds has again been on a moderate scale, the increasing unrest in important branches of industry tending to retard progress in the home trades. In the export trade business has been fair, and shipments have again been fairly active. **Bleaching Powder** has had a moderate inquiry, and is £10. to £11. per ton for use in the United Kingdom, and £11. per ton for export. **Calcium Chloride** has been in fair request, and is £5. 17s. 6d. per ton. **Caustic Soda** has been rather more in demand, and has again been shipped freely on export account. The price is £20. 7s. 6d. to £21. 7s. 6d. per ton for 76%, carriage paid, for the home trade, and £20. 10s. per ton for export. **Bicarbonate of Soda** has been in good request for home-trade uses, and has had a fair shipment for exportation. It is £10. 10s. per ton for use in the United Kingdom. **Soda Crystals** have been steadily called for. The price is £5. 5s. per ton for the home trade. **Nitrate of Soda** has been quiet, and is £13. 5s. to £13. 10s. per ton. **Borax** has sold rather freely; commercial crystals are £27. per ton, and powdered £28. Higher grades are: Crystals £31. per ton, powdered £32. per ton, carriage paid in the United Kingdom. **Saltcake** has been in fair demand for home-trade uses. It is £4. 10s. to £5. per ton for the home trade, and £5. 10s. to £6. per ton for export. **Bichromate of Soda** has been quiet, and is 4½d. per lb. **Ammonia Alkali** has been rather more in demand for use in the U.K., and has had an active shipment for foreign ports. It is £7. 12s. 6d. per ton for use by the home trade, and £8. per ton for export. **Hyposulphite of Soda** has been more inquired for; it is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial, and £15. to £17. per ton, in 1cwt. kegs for photographic. **Sulphide of Soda** has

been but little in demand; solid is £16. per ton, and crystals £10. **Chlorate of Soda** has been very quiet, and is 3d. to 3½d. per lb. **Phosphate of Soda** has had a limited sale, and is £15. to £16. per ton. **Prussiate of Soda** has again been in moderate request, and is 7d. to 8d. per lb. **Yellow Prussiate of Potash** has had a small but steady sale, and is 1s. 4d. to 1s. 4½d. per lb. **Red Prussiate** has been quieter, and is 4s. per lb. **Carbonate of Potash** has had a limited demand, and is £26. to £32. per ton, according to quality. **Nitrate of Potash** has had a very fair sale, and is £33. to £35. per ton for refined. **Chlorate of Potash** has been but little in request, and is 4d. to 4½d. per lb. **Caustic Potash** has been inactive, and is £32. to £33. per ton. **Permanganate of Potash** has been steadily called for, and is 10d. to 10½d. per lb. **Bichromate of Potash** has had a moderate inquiry, and is 5¾d. per lb. c.i.f. to usual ports. **Salammoniac** has been quieter; first quality is £63. per ton; second quality is £60., and third £57. **Sulphate of Ammonia** has been but little in request; the reduced prices are—£14. 15s. per ton for neutral, and £13. 12s. per ton for ordinary, to the end of August. **Carbonate of Ammonia** has been in fair demand, and is 4d. per lb. **Muriate of Ammonia** has moved but slowly, and is £32. to £33. per ton. **Magnesia** has had a very fair inquiry. **Carbonate** is £2. 5s. per cwt., and **Sulphate** £5. to £6. per ton. **Alum** has had a steady sale; for the home trade £12. to £13. per ton is quoted, and for export, £11. 10s. to £12. per ton. **Sulphate of Alumina** has had a very moderate inquiry, and is £8. to £12. per ton, according to quality. **Sulphur** has been in good request; flowers are £10. per ton, roll is £8. 10s. per ton, rock, £8. to £8. 10s. per ton, and American £5. to £5. 10s. per ton. **Tartaric Acid** has sold rather more freely, and is 1s. 4d. to 1s. 4½d. per lb. **Cream of Tartar** has been in good request, and is £4. 10s. to £4. 13s. per cwt. **Boric Acid** has been steadily called for; commercial crystals are £50. per ton, and powdered £53., and £2. per ton more, if in casks. **Citric Acid** has been more in request, and is 1s. 9d. to 1s. 10d. per lb. **Oxalic Acid** has been inactive, and is 6¼d. to 6½d. per lb. **White Acetate of Lead** has been but little in demand, and is £42. to £43. per ton. **Sulphate of Copper** has moved but slowly for use by the home trade, but has had a fair shipment for overseas ports; the price has eased; it is £26. 2s. 6d. to £26. 5s. per ton, less 5%, in casks, f.o.b. at Liverpool. **Arsenic** has been neglected; white powdered is £71. per ton.

WEST OF SCOTLAND CHEMICALS. Wednesday.

Business in chemicals still remains quiet, both on home and export account. Prices are inclined to be easier, but inquiry continues to be a negligible quantity. The general situation does not promise an immediate revival in the chemical-using industries, but there is some little activity in the export branch, mainly in fulfilling contracts. Quotations at Glasgow, unless otherwise stated, are as follows. **Alum,** little doing, and in small demand; prices have been reduced and now stand at £12. 10s. for lump, and ground £12. per ton. **Arsenic** continues in short request, and supplies are still very scarce; it is quoted on spot at £77. net. **Barium Chloride** remains very quiet, despite the recent reduction to £15. 15s. per ton. **Bleaching Powder** does not show much movement, and the quotation still stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax,** granulated is on offer at £26. 10s. per ton net, in 2cwt. bags. **Calcium Chloride,** 70—75 per cent. solid, £5. 12s. 6d. per ton. **Citric Acid** is a declining market, and the price has been further lowered to 1s. 8¼d. per lb., less 5%. **Copper Sulphate** is but little in request at last week's figure of £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar** firm, with better inquiry, and the price continues steady at £4. 10s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in quieter demand; brown steady at £40. 10s. per ton, net, and white lower at £40. 10s. per ton, net. The market for **Magnesium Chloride** is slow, but last week's quotation of £3. has reached to £3. 5s. for spot material. **Oxalic Acid,** at 6½d. per lb., is dull, but this price is still held. **Paraffin Wax** experiences a fair export trade at 2¾d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull at the rather easier figure of 1s. 4½d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1. 11s. per ton, but business is nominal. **Sodium Bichromate** remains steady, with business on the basis of 4½d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2cwt. bags; and £11. 10s. in 1cwt. kegs. **Tartar Emetic,** 43—44%, in fair request at 1s. 1½d. **Tartaric Acid** still shows a quieter tendency at 1s. 3¼d. per lb.

IMPORTS OF CHEMICAL PRODUCTS

At the Principal Ports of the United Kingdom.

DYESTUFFS (ARTIFICIAL)—
Unspecified
Adelaide, 28 pkgs. (pt.) £23.; Barbados ,2 cs., £13.; Bluff, 1 cs. (pt.), £22.; Boulogne, 18 pkgs., £554.; Dunediu, 1 kg., £10.; Durban, 1 cs., 1 pkg., £42.; Durban (F.), 1 cs. (pt.), £5.; Irish Free State, 1 cs., £27.; Levuke, 1 cs., £25.; Madras, 1 cs. (pt.), £14.; Melbourne (F.), 1 kg., £27.; Melbourne, 1 kg., £27.; New York, 1 cs. (pt.), £8.; Singapore, 3 cs., £23.; Sydney, 9 pkgs., £458.; Sydney (F.), 14 kgs., £237.; Valencia, 1 cs., £74.

ETHER—
Cape Town, 1 cs., £18.; East London, 4 cs. (pt.), £18.; Madras, 4 cs., £22.; Malta, 6 cs., £27.; Singapore, 3 cs., £8.

ETHYL CHLORIDE—
Durban, 1 cs., £18.
Wellington, 1 cs., £8.

FERTILISERS (*otherwise undes.*)—
Baltimore, 50 t., £325.
Durban, 3 c., £5.

GALLIC ACID—
Brisbane, 1 c., £8.

GLYCERINE—
Barcelona, 1 t. 1 c., £96.; Beira, 3 c., £13.; Cape Town (crude), 5 t. 1 c., £258.; Demerara, 1 c., £5.; Fremantle, 5 c., £22.; Jamaica, 3 c., £13.; Lisbon, 1 t., £80.; New York (crude), 35 t. 9 c., £1,636.; Rio de Janeiro, 1 c., £5.

HYDROCHLORIC ACID—
Alexandria, 1 c., £7.; Karachi, 6 c., £25.; Melbourne, 1 cs., £6.; Rangoon, 5 c., £16.; Wellington, 4 c., £15.

HYDROFLUORIC ACID—
Adelaide, 1 cs., £8.
Hong Kong, 2 cs., £16.

HYDROGEN PEROXIDE—
Alexandria, 2 cs., £19.; Beira, 5 cs., £44.; East London, 8 cs., £16.; Jamaica, 3 cs., £21.; Kilindini, 3 cs., £9.

HYPOPHOSPHITE SALTS (*otherwise undescribed*)—
Genoa, 13 cs., £229.

IODINE—
Buenos Ayres, 2 cs., £207.
Calcutta, 1 cs., £53.

IRON AMMONIUM CITRATE
Auckland, 1 cs., £16.
Sydney, 1 cs., £13.

IRON SALTS (*otherwise undescribed*)
Calcutta, 1 cs. (pt.), £14.

LEAD ARSENATE—
Helsingborg, 2 drms., £13.
Sydney, 26 kgs., £77.

LEAD NITRATE—
Beira, 2 cs., £21.

LEAD OXIDE—
Genoa, 1 drm., £66.

MAGNESIA—
Auckland, 10 cs., £24.; Alexandria, 5 cs., £150.; Irish Free State, 55 pkgs., 3 cs., £530.

MAGNESIA—
Lyttleton, 10 cs., £24.; Pt. Said, 5 cs., £150.; Pt. Swettenham, 2 cs., £5.; Rio de Janeiro, 4 cs., £31.; Switzerland, 2 cs., £5.; Wellington, 20 cs., £48.

MAGNESIA (CALCINED)—
Buenos Ayres, 1 cs., £12.

MAGNESIUM CARBONATE—
Buenos Ayres, 10 cs., £35.; Calcutta, 1 cs., £6.; Rio de Janeiro, 6 cs., £24.; Trinidad, 3 cs., £11.; Wellington, 6 cs., £8.

MAGNESIUM CITRATE—
Calcutta, 1 cs., £12.
Gibraltar, 5 cs., £75.

MAGNESIUM SULPHATE—
Auckland, 1 t. 14 c., £43.; Barbados, 3 c., £6.; Cape Town,, 5 c., £7.; Delagoa Bay, 4 c., £5.; Demerara, 10 c., £8.; Dunedin, 1 t. 3 c., £28.; Durban, 14 c., £18.; East London, 11 c., £16.; Lyttleton, 3 t. 5 c., £81.; Melbourne, 1 t. 2 c., £29.; Pt. Elizabeth, 14 c., £18.; Wanganui, 5 c., £7.; Wellington, 1 t. 19 c., £54.

MANGANESE BORATE—
Antwerp, 6 cs., £29.
Christchurch, 1 ck., £8.

MERCURIALS (*otherwise undes.*)—
Calcutta, 1 cs., £28.

MERCURY SUBCHLORIDE—
Coconada, 1 cs., £24.

METHYL SALICYLATE—
Auckland, 1 cs., £7.

NICKEL OXIDE—
Amsterdam, 1 cs., £6.

NITRIC ACID—
Alexandria, 1 c., £9.; Auckland, 2 c., £5.; Karachi, 2 c., £8.; Rangoon, 5 c., £22.; Sydney, 1 c., £5.; Wellington, 15 c., £43.

PARALDEHYDE—
Sydney, 2 cs., £11.

PHOSPHORIC ACID—
Adelaide, 4 cs., £8.; Fremantle, 2 cs., £5.; Melbourne, 10 cs., £35.; Sydney, 50 cs., £146.; Wellington, 2 cs., £6.

PHOSPHORUS SESQUISULPHIDE
Buenos Ayres, 200 cs., £2,156.
Monte Video, 40 cs. (pt.), £431.

POTASSIUM BROMIDE—
Cape Town, 2 cs., £8.
Calcutta, 2 kgs., £10.

POTASSIUM CARBONATE—
Ahwaz, 2 kgs., £6.

POTASSIUM CHLORATE—
Bushire, 2 c., £8.

POTASSIUM CITRATE—
Auckland, 1 cs., £15.

POTASSIUM CYANIDE—
Shanghai, 2 cs., £22.
Singapore, 3 cs., £34.

POTASSIUM IODIDE—
Beira, 1 cs., £83.; Calcutta, 1 cs., £88.; Madras, 22 cs. (pt.), 1 cs., £94.; Melbourne, 1 cs., £87.; Opobo, 10 cs., £83.; Rio de Janeiro, 3 cks. (pt.), £66.; Sekondi, 1 cs., £11.

POTASSIUM METABISULPHITE—
Antwerp, 10 cs., £75.; Dunedin, 4 kgs., £22.; Melbourne, 12 cs., £39.; Sydney, 2 cs., £23.

POTASSIUM PERMANGANATE—
Auckland, 1 drm., £5.
Calcutta, 1 drm., £7.
Lyttleton (F.), 2 drms., £9.

POTASSIUM PRUSSIATE—
Barcelona, 1 ck., £18.

POTASSIUM BINOXALATE—
Sydney (F.), 2 kgs., £14.
Sydney, 2 kgs., £15.

PYROGALLIC ACID—
Danzig, 1 pkg., £11.
Montreal, 2 cs., £46.

ROCHELLE SALTS—
Melbourne, 1 cs., £5.

SALAMMONIAC—
Auckland, 7 c., £24.; Fremantle, 2 c., £6.; Napier, 2 c., £6.; Sydney, 2 c., £6.

SALICYLIC ACID—
Hong Kong, 1 cs., £10.
Wellington, 1 kg., £12.

SALTCAKE—
Bilbao, 150 t., £731.

SALTPETRE—
Calcutta, 5 c., £16.; Rio de Janeiro, 1 t., £43.; Seychelles, 5 c., £11.; Sydney, 1 t., £125.

SHEEP DIP—
Bluff, 4 t., £177.
Lyttleton, 9 t. 10 c., £442.
Pt. Madryn, 47 t. 2 c., £2,500.

SILVER NITRATE—
Bombay, 1 cs., £100.
Hong Kong, 1 cs., £175.

SODA CRYSTALS—
Calcutta, 15 c., £5.
Perth, 5 crts., £19.

SODIUM ARSENITE—
Durban, 1 t. 3 c., £82.

SODIUM BENZOATE—
Calcutta, 10 cs., £117.
Shanghai, 2 cs., £23.

SODIUM BICARBONATE—
Arequipa, 10 c., £9.; Auckland, 4 c., £8.; Buenos Ayres, 6 c., £14.; Calcutta, 18 c., £54.; Colombo, 1 t., £43.; Durban, 10 c., £13.; East London, 4 c., £6.; Hong Kong, 1 c., £5.; Lima, 9 c., £12.; Pt. Elizabeth, 1 t. 4 c., £37.; Suva, 10 c., £6.; Vancouver, 2 c., £5.

SODIUM BISULPHITE—
Auckland, 1 t., £20.; Belawan, 2 t. 10 c., £48.; Pt. Swettenham, 2 t. 10 c., £50.; Sourabaya, 2 t., £38.

SODIUM HYPOSULPHITE—
Durban, 1 t., £17.
Malta, 6 c., £5.

SODIUM NITRATE—
Calicut, 10 t., £145.

SODIUM PEROXIDE—
Adelaide, 1 cs., £7.

SODIUM PYROPHOSPHATE—
Sydney, 10 c., £23.

SODIUM SALICYLATE—
Auckland, 1 cs., £7.
Calcutta, 2 cs., £14.

SODIUM SULPHATE—
Barbados, 1 t., £7.; Demerara, 1 t. £7.; Irish Free State, 8 c., £8.

SODIUM SULPHITE—
Malta, 6 c. £7.; Singapore, 3 cks., £14.; Tokio, 2 t., £51.

SODIUM TARTRATE—
Calcutta, 6 c., £31.

SULPHUR CHLORIDE—
Brussels, 16 crbys., £29.

SULPHURIC ACID—
Alexandria, 1 c., £7.; Amsterdam, 6 c., £7.; Karachi, 2 c., £8.; Pt. Sudan, 2 t., £33.; Rangoon, 5 c., £16.; Sekondi, 1 t. 18 c., £38.; Wellington, 1 t. 5 c., £55.

SUPERPHOSPHATE—
Channel Islands, 5 t., £25.
Durban, 187 t. 11 c., £1,449.
Grenada, 6 t., £27.

TARTARIC ACID—
Adelaide, 1 t., £131.; Auckland, 6 c., £39.; Barbados, 1 c., £11.; Calcutta, 1 c., £13.; Cape Town, 4 c. (F.), £29.; Callao, 6 c., £47.; Delagoa Bay, 2 c., £20.; Durban, 1 c. (F.), £10.; East London, 1 c., £9.; Gothenburg, 2 c., £13.; Hamburg, 6 c., £39.; Lima, 2 c., £19.; Lyttleton, 12 c., £78.; Melbourne, 2 t., £261.; Montreal, 2 t. 10 c., £327.; Napier, 1 c., £11.; Pt. Elizabeth, 10 c., £62.; Pt. Elizabeth (F.), 2 c., £20.; Riga (F.), 1 t. 10 c., £200.; Samarang, 3 c., £20.; Sourabaya, 3 c., £20.; Sydney, 10 c., £75.; Vera Cruz, 1 t., £131.

TIN OXIDE—
Brussels, 5 cks., £235.

TURPENTINE—
Auckland, 8 cs. (pt.), £6.

URANIUM ACETATE—
Sydney, 1 cs., £5.

ZINC OXIDE—
Calcutta, 10 kgs., £39.; New York, 2 cks., £10.; Otago, 1 c., £6.; Wellington, 2 cs., £9.

Week ending July 7.

ANTIMONY—
Rio de Janeiro, 2 t.

BEESWAX—
Irish Free State, 1 t.

BONE ASH—
Sydney, 10 c.

CARNAUBA WAX—
Irish Free State, 1 t.

CASEIN—
Italy, 1 t.: Vera Cruz, 9 t. 14 c.

CERESINE WAX—
Sydney, 6 c.

FULLER'S EARTH—
Montreal, 40 t.

GLUE, SIZE AND GELATINE—
Adelaide, 17 c.; Alexandria, 4 t. 1 c.; Antwerp, 1 t. 1 c.; Auckland, 11 c.; Barbados, 4 c.; Bombay, 1 t.; Bordeaux, 5 t.; Calcutta, 2 t. 1 c.; Christchurch, 1 c.; Iddo, 1 c.; Dunedin, 1 c.; Durban, 12 c.; East London, 1 c.; Hong Kong, 1 c.; Irish Free State, 4 c.; Kobe, 53 t. 1 c.; Kilindini, 5 c.; Larache, 15 c.; Madras, 1 t.; Manilla, 1 t.; Melbourne, 2 c.; Montreal, 3 t.; Perth, 5 c.; Pt. Elizabeth, 8 c.; Rangoon, 6 c.; Rotterdam, 3 c.; St. Helena, 1 c.; Shanghai, 2 c.; Shanghai, 1 t. 1 c.; Tampico, 1 t.; Toronto, 4 t. 5 c.; Vancouver, 1 t. Vera Cruz, 15 t. 2 c.; Yokohama, 17 t. 10 c.; Sydney, 2 t. 5 c.

IRON OXIDE—
Antwerp, 30 t.

LEAD ASHES—
Antwerp, 7 t.

MINERAL WAX—
Havre, 17 c.

PARAFFIN SCALE—
Cape Town, 1 t.

PLUMBAGO—
Dunedin, 10 c.; Rio de Janeiro, 1 t. 10 c.; Valencia, 1 t.

QUININE—
Beira, 170 oz.; Calcutta, 1,000 oz.; Dar-es-Salaam, 2,048 oz.; Demerara, 5,208 oz.; Irish Free State, 38 oz.; Lyttleton, 25 oz.; Madras, 27 oz.; Rio de Janeiro, 966 oz.; Sydney, 232 oz.; Tanga, 12 oz.

SALT—
East London, 6 c.; Hong Kong, 8 c.; Iquique, 6 c.; Irish Free State, 1 c.; Kilindini, 1 c.; Malta, 11 c.; Madras, 9 c.; Penang, 2 c.; Pt. Swettenham, 2 c.; Pt. Said, 3 c.; Pt. Swettenham, 2 c.; Rabat, 1 t. 12 c.; Rangoon, 8 c.; Salonica, 2 c.; Singapore, 1 t. 1 c.; Sekondi, 1 c.; Sydney, 9 t. 13 c.

SHELLAC—
Italy, 1 t. 1 c.

SOAP—
Accra, 19 t. 2 c.; Adelaide, 8 c.; Ahwaz, 4 c.; Alexandria, 14 c.; Amsterdam, 1 t. 2 c.; Antwerp, 1 t. 11 c.; Auckland, 10 c.; Bagdad, 3 c.; Beira, 4 c.; Bilbao, 9 c.; Bombay, 6 t. 16 c.; Buenos Ayres, 3 c.; Boulogne, 8 c.; Brussels, 1 c.; Calcutta, 10 c.; Calabar, 5 t. 7 c.; Cape Town, 2 c.; Cologne, 12 c.; Colombo, 7 t. 14 c.; Christchurch, 5 c.; Copenhagen, 1 c.; Dominica, 1 t.; Durban, 4 c.; Hong Kong, 4 c.; Irish Free State, 2 t. 5 c.; Jamaica, 8 t.; Karachi, 5 t.; Kilindini, 2 t. 11 c.; Larache, 1 t.; Lyttleton, 1 c.; Madras, 18 c.; Malta, 2 c.; Melbourne, 5 c.; Monte Video, 1 c.; Newcastle, 4 c.; Penang, 6 c.; Pt. Elizabeth, 1 t. 8 c.; Pt. Said, 11 c.; Quilimane, 1 c.; Rabat, 9 t. 18 c.; Rangoon, 8 c.; Rotterdam, 1 t. 12 c.; Santander, 7 c.; St. Kitts, 2 t. 10 c.; Santos, 1 c.; Sekondi, 112 t. 15 c.; Seville, 3 c.; Shanghai, 5 c.; Singapore, 14 c.; Stockholm, 4 c.; Sydney, 10 c.; Timaru, 1 c.; Trinidad, 11 t. 10 c.; Trondhjem, 9 c.; Vancouver, 1 c.; Vera Cruz, 8 c.; Yokohama, 1 t. 12 c.

TALLOW—
Shanghai, 5 c.

WHITE LEAD—
Adelaide, £141.; Antwerp, £19.; Auckland, £91.; Bangkok, £331.; Bombay, £40.; Brisbane, £240.; Cape Town, £47.; Channel Is., £32.; Fiji Islands, £22.; Gisborne, £70.; Hobart, £49.; Irish Free State, £297.; Invercargill, £75.; Launceston, £13.; Madras, £2,009.; Malta, £32.; Melbourne, £238.; Pt. Elizabeth, £8.; Rio de Janeiro, £5.; Rotterdam, £21.; Shanghai, £8.; St. Thomas, £30.; Singapore, £13.; Sydney, £663.; Tocopilla, £34.; Townsville, £24.

MANCHESTER.

Week ending July 5.

BITUMEN—
Bombay, 11 cs.

DYESTUFFS (ARTIFICIAL)—
Unspecified
India, 1 cs.

GLUE—
Alexandria, 10 t.

MINERAL WHITE—
Spain, 5 bgs.

SALT—
Ghent, 2,000 sks.

NEWCASTLE-ON-TYNE

Week ending July 7.

ANTIMONY—

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	**19s. 6d.**	**24s.**
Half-yearly (26 numbers)	**10s. 6d.**	**13s.**
Quarterly (13 numbers)	**5s. 6d.**	**7s.**

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."

Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

THE WORK OF THE A.B.C.M.

THAT the Association of British Chemical Manufacturers has amply justified its existence, and is doing work of inestimable value for the chemical industry of the country as a whole, was clearly illustrated in the proceedings at the seventh annual general meeting, held in London last Thursday The solidarity now existing in the ranks of the larger, and to a considerable extent of the smaller, manufacturers seems destined to find its most spectacular expression in the comprehensive exhibit being arranged for the Chemical Section at the British Empire Exhibition next year. As Dr. Levinstein pointed out, such an exhibit cannot fail to impress the foreign visitor—and in a way that a multiplicity of exhibits by private firms could hardly do—with the fact that the whole of the resources and determination of the country are behind the attempt to establish all branches of the chemical industry in a flourishing condition in Great Britain. It is a matter for congratulation that through the activities of the Association, the restrictions in the use of alcohol for chemical manufacturing purposes have been considerably relaxed, and it is to be hoped and expected that full advantage will be taken of the new concessions. The grave note sounded by Sir Max Muspratt in discussing the Continental situation will undoubtedly be echoed by all serious business men. The immediate stimulus to our chemical trade accruing from the restriction of German activities in the Ruhr district, has by no means compensated for the injury to our slowly recovering overseas trade that has been inflicted by the dislocation and uncertainties of the moment. The solution of the Ruhr and reparations problem is now occupying the attention of the statesmen of all European countries, and until a satisfactory solution is arrived at, stability in international trade cannot be attained. A further important matter discussed at the general meeting was the wisest attitude to be adopted by manufacturers and traders in their attempt to secure lower railway rates. The fundamental question is whether resort should be had to direct frontal attack against the railway companies before all the possibilities of arriving at agreement by negotiation are exhausted. The consensus of opinion furnished a negative reply to the above question, and we ourselves are inclined to agree with the general opinion, though not entirely on the grounds advanced by the Right Hon. J. W. Wilson.

CAUSTIC SODA FROM SODIUM SULPHATE.

An interesting investigation has recently been carried out at the Massachusetts Institute of Technology to determine the practicability, from a commercial standpoint, of recovering caustic soda and sulphuric acid of satisfactory concentrations and purity by the electrolysis of sodium-sulphate solutions. The work was undertaken at the request of the Viscose Company, of America, who produce large amounts of sodium sulphate as a by-product, and has produced results which indicate that, operating under suitable conditions, the total cost of production per pound of caustic soda compares very favourably with that from sodium chloride. The actual experiments were carried out by H. V. Atwell and T. Fuwa, and the detailed results are given in the *Industrial and Engineering Chemistry*, June, 1923. Owing to the rather surprising lack of data in the literature on the behaviour of sodium sulphate as an electrolyte, the workers had at the outset to determine the specific gravity and electrical conductivity of fairly concentrated sodium-sulphate solutions at elevated temperatures, but the investigations were continued until a suitable type of cell was elaborated and all the fundamental factors governing the electrolysis were established. Stated briefly, the process recommended is as follows: The cell follows in principle the design of the Allen-Moore caustic soda-chlorine cell. The electrodes, consisting of two highly perforated metal plates each covered on the inner surface with a sheet of asbestos paper, are clamped against the opposite sides of a thin rectangular frame of non-conducting material, thus forming the electrolysing chamber. Sodium-sulphate solution is fed into the interior of this chamber, and under its own gravity head of a few inches flows out continuously through the diaphragms and electrodes carrying the products of electrolysis along with it. The anode is made of perforated sheet iron, and the cathode of perforated chemical sheet lead. Operating with a liquid head of 4 to 6 inches, with a current density of 100 amperes per square foot, and with an electrolyte containing 22 per cent. of sodium sulphate at 80° to 90° C it is possible to obtain a current efficieny of 85 per cent., an operating voltage of 4.3 volts, and a yield of 0.65 pound of caustic soda and 0.79 pound of sulphuric acid per kilowatt hour. The caustic soda is in the form of a 6.5 per cent. solution containing 15 per cent. of sodium sulphate, which can apparently be concentrated to practically pure sodium hydroxide in an ordinary caustic evaporator equipped with salt catchers. The sulphuric acid is in the form of an 11 per cent. solution containing about 13 per cent. of sodium sulphate which cannot readily be removed. Of course, the value of the two anode products—sulphuric acid and oxygen—is considerably less than that of the chlorine from the sodium chloride process, but where plentiful supplies of waste sodium sulphate are available, and where the oxygen can be used or sold locally without compressing into cylinders, the process would appear to be decidedly attractive.

THE CARACRISTI LOW-TEMPERATURE PROCESS.

The description of the Caracristi process of low-temperature carbonisation that we published a fortnight ago has aroused considerable interect. The remarkable claims made for the process, the apparent absence of serious engineering difficulties, and the fact that the firm of Henry Ford have definitely adopted the method and are already constructing a large plant at the Ford motor-car factory at Walkerville, all conspire to make the Caracristi process the object of serious attention by British fuel technologists. It appears that the process has been investigated continuously for nearly three years now, and that after the ingenious conveyor system had been perfected, the minor difficulties subsequently encountered were easily surmounted. It will be remembered that the conveyor system, upon which the roughly pulverised raw coal travels, is constructed of three strands of cast-iron plates held together by steel hinge-pins with flanged ends, and with the hinge joints overlapping so that no cracks can be forced. These conveyors float on and travel over the molten lead. The process is continuous, and the claim is made that carbonisation can actually be completed in five minutes. No mention is made of any difficulties arising from the oxidation of the lead, which is kept in a molten state, at 1,200° F., for weeks on end, and this, as our engineer-correspondent pointed out two weeks ago, is somewhat difficult to explain, unless, as is possible, the construction of the plant is such that the lead is at no point exposed to the external atmosphere. The most recent news about the Caracristi process is that successful tests have just been completed at the Ford by-product plant at Detroit to determine whether the semi-coke resulting from the carbonisation can be used in making foundry coke.

BRITISH PROGRESS IN NITROGEN FIXATION.

The announcement made by Mr. Kenneth M. Chance, the managing director of the British Cyanides Company, at the annual general meeting held on Wednesday, that he hoped the passage of another few months would witness the successful large-scale operation of the barium cyanide process for the fixation of atmospheric nitrogen, makes very welcome reading. Whether the atmospheric nitrogen can be fixed at a sufficiently low price to enable the resulting cyanide compounds to be converted into ammonia at a price which will enable the ammonia to compete with the directly prepared synthetic product, remains to be seen, but in any case the direct manufacture of cyanogen products is a notable achievement which will help in the conservation of the world's natural resources of fixed nitrogen. The manufacture of potassium permanganate by electrolysis has presented many practical difficulties, but, according to Mr. Chance, all these difficulties have been surmounted, and a plant for the purpose will shortly be in operation at the Tat Bank works. Both achievements are a great tribute to the efficiency and courage of British manufacturers, chemists, and chemical engineers.

THE ASSOCIATION OF BRITISH CHEMICAL MANUFACTURERS.

ANNUAL GENERAL MEETING.

THE Seventh Annual General Meeting was held at the Chemical Society's Rooms, Burlington House, Piccadilly, W. 1, on Thursday, July 12. Sir Max Muspratt, Bart., Chairman of the Association, presided. The Chairman, in proposing that the report and the accounts of the Association be adopted, said: There is not a single member who is not very proud of the Association, and its sphere of usefulness is constantly increasing.

In spite of being chemical manufacturers, we have in recent years overcome somewhat the modesty of previous eras of chemical industry, and we believe that we have a message of a two-fold nature to give to the nation. We have a duty to perform in instructing Ministers of the Crown and other members of the Government and the Civil Service as to what they ought to know about this most important industry. We have also to impress upon the nation at large that in Great Britain the chemical industry is a very important national asset and, like every other important national asset, it has got to go forward or go back. We intend, by every means in our power, to further the progress of this industry by getting the public and the Government to understand what it means and how it should be treated.

The British Empire Exhibition.

The British Industries Fair of 1923 is dealt with in the report in an efficient manner, but I think I might accentuate the fact that in the British Industries Fair, both this year and on previous occasions, we have tried to carry out the policy of showing the close interlocking of the various branches of the chemical industry. The British Industries Fair is, we hope and believe, an annual factor, but next year when the British Empire Exhibition also takes place we felt that it would be calling too much upon our members to make an adequate chemical section on both those occasions and so, although a small minority objected, we are not taking any part in the British Industries Fair of next year. In the British Empire Exhibition of 1924 we are taking a very great part. We intend the Chemical Section of the British Empire Exhibition to be a complete survey of Great Britain's services to chemistry, from top to bottom. In carrying this out we are very much indebted to Dr. Levinstein for the manner in which, as Chairman of the Sub-committee, he has taken up the idea and brought it home to all those who can assist. When I tell you that the Royal Society is going to take part in an Exhibition I think you will admit that we are bringing even the academic section of chemistry into the services of mankind and the Empire. Sir Herbert Jackson is *liaison* officer in conjunction with our General Manager, to see that the most complete linking up in absolute harmony of every aspect of chemistry is duly and properly carried out at the British Empire Exhibition next year.

Gravity of the Ruhr Situation.

With regard to the Continental situation, I need only deal with it purely from the aspect of chemical industry. The whole position of the Ruhr is one which the chemical industry, especially the fine chemicals and the dyestuff branches of the industry, has to look upon with great apprehension. There are superficial advantages in having competitors closed, but I am sure that nobody with the broad training of a chemist will for a moment take that aspect; it is bigger and larger than that. On the purely material side, it is even better to have the chemicals in the hands of a competitive manufacturer than to have them in the hands of an irresponsible Government Department, and when that irresponsible Government Department is not even in this country, I need hardly say that what is going to happen to those dyes and other chemicals which have been taken by the French Government is causing grave doubt and grave uneasiness in the minds of everyone connected with the Council of the Association of British Chemical Manufacturers. We have taken every step that we think humanly possible; we have kept all the necessary Government Departments in this country well advised. I should like to repeat here the very timely warning which Mr. Woolcock gave to the dyers and colourists, that what had happened in the Ruhr was a reminder to the dye-users of the very unstable foundation upon which their supplies of dyes still rested, and that the Government of this country was free at any rate, from one grave anxiety by the fact that the great textile industry could go on with the assistance of the British dye manufacturers, whatever happened on the Ruhr.

Co-operation between Chemical Manufacturers.

With regard to the Dyestuffs Act, I will only refer to the agitation for the repeal of that Act, and to ask if the real trouble of the textile industry is not the high price of cotton. I am confident that last year great advances were made in our dyestuff industry not only on the technical and business side, great as those are, but towards a better understanding of the economic position. What is wanted is patience, co-operation, and goodwill. On the subject of co-operation, I know I am speaking for everyone occupied with the heavy chemical industry in assuring Sir William Alexander and his colleagues in other branches of the dye industry that the heavy chemical industry does desire to assist and co-operate with them in every possible way. Co-operation has proceeded appreciably but, if I may just drop a gentle hint, I believe that co-operation can be speeded up to the advantage of the heavy chemical industry and to the very great advantage of the dye industry.

Turning to the question of alcohol, I should like to say how deeply we are indebted to Mr. Carr for the way in which he has handled this problem in conjunction with the Committee. After long negotiations had been carried out, further concessions have been made which I understand Mr. Carr and the Committee are convinced are as far as any manufacturers can reasonably ask the Customs officials at the present time to go.

Mr. R. G. Perry, C.B.E., in the absence, owing to illness of the Vice-Chairman, Sir William Pearce, seconded the resolution. He said there was only one point to which he would like to refer. It was the paragraph in the report which read as follows:—"The Council records with satisfaction and appreciation the honour which has been conferred by His Majesty the King upon its Chairman, Sir Max Muspratt, Bart." He would like to say for that meeting that they all wished to congratulate their Chairman upon that honour.

The Treasurer (Mr. C. A. Hill), in commenting on the accounts, said that in case it should be thought they were working on too narrow a margin, he would like to put forward the view that the Association belonged to the members and it should be worked very much on the lines of a club; that is to say, the subscriptions of the members should be based so that they get the most efficient service possible without any stint, and yet they were not building up too big a reserve for posterity; that is to say, they were not being asked to pay more than they were receiving, so that if the Council could give a satisfactory service, and yet end up with a small balance, that was a result which was satisfactory.

Dr. E. F. Armstrong, F.R.S., said that the Association had certainly done well during the year, but it was desirable that the chemical industry should try to stand on its own feet and not rely too much on Government patronage. It was only by research and by its technical work that they could get an advantage in the future.

Sir William Alexander said his company had received from the large members of the heavy chemical industry in recent times very real and concrete assistance in bringing down the prices of their products. He felt certain that their industry was going to pull through.

The Transport of Chemicals by Rail.

The Rt. Hon. J. W. Wilson said he was very glad that the Transport Committee had pursued the policy of negotiation and, as far as possible, co-operation in the matter of railway rates and services. He foresaw that during the next twelve months, and probably over a longer period, the lines were being set for a battle between two sets of business men—shareholders of the railway companies on the one hand, and the traders on the other. The carriers of the country were faced with a great burden, a legacy of the war from the Government to them to maintain certain rates of wages. They were paying two or three times as much as in pre-war times for labour; and Labour was quite ready to appreciate and, he believed, to a large extent they did co-operate with the railway companies. At the same time, if Labour saw that there was a chance of their fighting each other in public, they would seize the opportunity for using all the arguments to their advantage and, incidentally, to reflect on other industries besides the railway companies. Therefore, he was

sorry the invitation had gone out to join hands, and that the Federation of British Industries had hastened to court straight away. He hoped that they, as another set of traders, would, at any rate, pause before they joined issue.

Relaxation of Restrictions on Industrial Alcohol.

Mr. F. H. Carr, C.B.E., F.I.C., referred to the alcohol question. The importance of alcohol to the fine chemical industry had perhaps never been stated, and yet it was the raw material, the coal tar, of the pharmaceutical chemical. The work that had been done by the Committee had only been possible because of an entirely new state of affairs at the Board of Customs and Excise, and it was to such people as Sir Horace Hamilton and Sir Robert Robertson that their thanks must be chiefly given. They had in the concessions which they had given shown that we are at the dawn of a new era as regards the use of alcohol in chemical manufacture. The concessions which had been made permitted manufacturers who are commencing to use alcohol to use quantities up to 100 gallons without any restrictions as regards their receivers, without the necessity of an officer being on the spot; and, provided adequate figures were shown as regards the destination of the alcohol that was being used, they were quite satisfied to leave it with fairly moderate restrictions.

Road Transport: A Weapon Against High Railway Rates.

Mr. Kenneth Chance, M.A., associated himself with the remarks of Mr. Wilson as to the question of transport. He did not believe they were going to do the least bit of good by fighting under the Act. He thought the Federation of British Industries had made a great mistake. But there was a way in which they could act on purely business lines. The Association by the co-operation of its members one with another could bring a great deal of pressure to bear on the railway companies. These latter were not without competition; they had very strong competitors in road transport, and the chemical industry was in an infinitely better position to take advantage of that than any of the heavy industries such as steel, iron, and coal, because while some of the members made purely heavy chemicals which were no doubt carried at very low rates, others made chemicals the railway rates on which were so high that road transport could be obtained at very much lower figures. His company had during the last six or twelve months made a great deal of use of road transport, and as a result of that they had obtained special rates from the railway companies on chemicals. If one small company by its individual efforts could do that, could they not make use of that form of co-operation together?

Significance of the B.E.E. Chemical Exhibit.

Dr. H. Levinstein, M.Sc., referring to the organisation of the Chemical Section of the Exhibition to be held at Wembley next year, said the mere fact that when they had a British Empire Exhibition the whole of the chemical exhibit could be dealt with by one organisation of this kind showed what an enormous stride the chemical industry had made in organisation since the last Exhibition of the same kind was held. People coming from abroad were apt not to attach too much importance to an exhibit made by a company, possibly because it was made by a company. But no person who took a long view would so regard their exhibit. They would know there was in it, beyond that desire of the State for having an Exhibition, a really strong, vigorous, intelligent, and organised school carrying out research on a large scale.

Mr. Bernard Hickson said he would like to endorse the remarks of Mr. Chance with regard to the railway companies. He would like to add that they had received very much assistance from the Traffic Department of the Association.

Mr. T. D. Morson said he hoped that publicity would remain in the forefront of the policy of the Association. The propaganda work of the chemical industry as a whole must obviously be carried on by the Association.

The Chairman, having briefly replied, then put the motion to the meeting, and declared the report and accounts unanimously adopted. The auditors (Messrs. Feasey and Co.) were reappointed, and the report of the scrutineers was received and adopted. That concluded the business of the ordinary meeting, which was followed by a special general meeting, when the amount of the annual subscription payable by members of the Association for the year 1923-1924 was fixed at four-fifths of the sums laid down in Article 17 of the Articles of Association.

Sir John Brunner, Bart., proposed, and Mr. R. G. Perry, C.B.E., seconded, a vote of thanks to the chairman, which was carried unanimously.

THE GRAVIMETRIC ESTIMATION OF IRON.

USE OF MERCUROUS AMMONIUM CHLORIDE.

THE usual method for the gravimetric estimation of iron is to precipitate the metal in the ferric state with ammonia, and to ignite the resulting ferric hydroxide to ferric oxide. This method of precipitation is not altogether satisfactory, for the $Fe(OH)_3$ separates out in the colloidal condition, is not an ideal material to filter, and has a pronounced tendency to revert to the soluble sol condition on washing with water. In addition it possesses a great absorptive capacity, especially for alkali salts. For accurate work by this method the precipitate must be dissolved up and reprecipitated several times, a procedure entailing not only much loss of time, but also increasing the liability to experimental error.

An inspection of the chemical literature during the past 30 years shows that the drawbacks of free ammonia have been fully realised by analysts, and that many proposals have been made for the replacement of the ammonia itself by its inorganic or organic derivatives. These are usually weaker bases than the free ammonia, and precipitate heavy metals either as insoluble complex salts or as hydroxides. Mention in this connection must be made of dimethylglyoxime suggested by Tschugaeff, dicyandiamin by Grossman, trimethyl-phenylammonium carbonate by Schirm, cupferron by Baudisch, and aniline and pyridine by Sanchez. Amongst the inorganic ammonia derivatives, Jannasch has suggested hydroxylamin and hydrazine.

According to B. Solaja (*Chemiker-Zeitung*, June 30, 1923) the mercury ammonium chloride usually known as "infusible white precipitate" $HgNH_2Cl$ is also a highly efficient ammonia substitute when used for the precipitation of iron salts. The precipitate is not colloidal, is easily filtered, and can be washed for any length of time without any of the precipitate going into solution. The following table of results shows that the precipitation is absolutely quantitative:—

Expt. No.	Actual Fe_2O_3 Present.	Fe_2O_3 Found by Precipitation with Ammonia.	Fe_2O_3 Found by Precipitation with "White Precipitate".
	Grammes.	Grammes.	Grammes.
1	0.1500	0.1498	0.1498
2	0.1500	0.1484	0.1499
3	0.1500	0.1503	0.1496
4	0.1500	0.1488	0.1496

For the above experiments a standard solution was prepared by dissolving 5.9981 grammes of the purest Fe_2O_3 in HCl., and making up to one litre; 25 c.c.s of this solution was used for each experiment.

Reagent Also Effects Quantitative Separation from Manganese.

Not only can iron be estimated quantitatively by means of "white precipitate," but it can also be separated quantitatively from manganese. The method was tested in a standard solution made by dissolving about 18 grammes of pure $MnCl_2.4H_2O$ in water and making up the solution to 1 litre. The mean of eight gravimetric estimations carried out by precipitation with hydrogen peroxide and ammonia, with ammonium persulphate and with sodium biphosphate gave its exact strength as 0.007068 gramme of Mn_3O_4 per c.c. The following table gives the results of the test experiments in the method:—

Expt. No	Ccs. $FeCl_3$.	Ccs. $MnCl_2$.	Fe_2O_3 Present.	Fe_2O_3 Found.	Mn_3O_4 Present.	Mn_3O_4 Found.
			Grammes.	Grammes.	Grammes.	Grammes.
1	25	25	0.1500	0.1513	0.1767	0.1770
2	25	25	0.1500	0.1511	0.1767	—
3	25	25	0.1500	0.1500	0.1767	0.1774
4	25	25	0.1500	0.1513	0.1767	0.1775
5	25	25	0.1500	0.1511	0.1767	—
6	25	25	0.1500	0.1508	0.1767	0.1756
7	50	25	0.3000	0.2998	0.1767	—
8	50	25	0.3000	0.3004	0.1767	—
9	50	10	0.3000	0.2993	0.0707	0.0711
10	50	10	0.3000	0.2997	0.0707	0.0706
11	25	1	0.1500	0.1495	0.0071	0.0074
12	25	1	0.1500	0.1502	0.0071	0.0071

The results recorded are very satisfactory, and further experiments are being conducted by B. Solaja to determine the utility of basic mercury ammonium compounds in other branches of analytical work.

SODIUM PERBORATE.

MANUFACTURE, PROPERTIES AND INDUSTRIAL APPLICATIONS.

By "Omega."

SODIUM perborate is one of the soluble salts of perboric acid, crystallises with four molecules of water, and contains 10.4 per cent. available oxygen. The acid itself has not yet been isolated owing to its instability, and differs from boric acid in that it contains an additional atom of oxygen. A solution of a perborate resembles a mixed solution of hydrogen peroxide and borax, inasmuch as decomposition takes place, the nascent oxygen liberated, immediately combining with the elements of water to form hydrogen peroxide. Temperature has a marked effect on the course of this reaction; in the cold, partial dissociation takes place, giving hydrogen peroxide and sodium meta-borate, whilst hot solutions evolve oxygen freely. The oxygen may also be liberated by the addition of organic or inorganic catalysts—*e.g.*, ferments, animal tissue, oxydases and manganese dioxide.

Sodium perborate was first prepared by Tanatar in 1898, who produced it by treating sodium ortho-borate with a concentrated solution of hydrogen peroxide, and its preparation has since been the subject of numerous patents. Jaubert (*Ger. Pats.* Nos. 193,559, 207,580) states that a high yield is obtained by the addition of a mixture of 12 parts of boric acid and 16 parts of sodium peroxide to 170 parts of a cooled solution of 7 per cent. sulphuric acid. The crystals are separated, washed, and dried with alcohol. Contamination with sodium sulphate may be avoided by the substitution of carbon dioxide for the sulphuric acid. A highly-pure product may be obtained by the addition of theoretical quantities of borax and sodium carbonate to a 5 per cent. solution of hydrogen peroxide. Hinkel et Cie (*Ger. Pat.* No. 283,894) suggest the auto-oxidation of aqueous solutions of borax and lime by means of aluminium amalgam in the presence of a current of oxygen.

Manufacture from Sodium Peroxide.

The two modern methods used in the manufacture of sodium perborate are: (I.) The interaction of sodium peroxide and sodium meta-borate; and (II.) electrolytic methods.

(1). The details of the first of these two processes have been patented by the Deutsche-Gold und Silberscheideanstalt, Frankfürt-on-Main, and also by the Société d'Oxylithe, and consist in dissolving 500 parts of sodium peroxide in 1,000 parts of water, the solution being kept cold throughout the operation. The solution is then saturated with carbon dioxide or filtered flue gases, and 500 parts of a saturated solution of sodium meta-borate added. The crystallised sodium perborate is separated by filtration and dried. A further addition to this patent proposes preparation by the addition of an alcoholic solution of hydrogen peroxide to an aqueous solution of borax. Tanatar (*Zeit. physikal Chem.* XXVI., p. 132) claims that a coarsely crystalline and stable product is obtained by pouring 140 parts of a solution containing 54 per cent. borax and 15 per cent. caustic soda into 1,000 parts of a 3 per cent. hydrogen peroxide solution, a yield of 88 per cent. of sodium perborate being obtained. Jaubert states that a highly-pure and stable perborate is obtained by adding sodium peroxide to an aqueous solution of hydrogen peroxide and boric acid, the reaction being according to the following equation—

$$2\,H_3BO_3 + Na_2O_2 + H_2O_2 = 2\,NaBO_3 \cdot 4\,H_2O$$

Electrolytic Production of Sodium Perborate.

(2). The pioneer researches in connection with the electrolytic production of sodium perborate are due to Arndt and Valeur, who prepared the pure product by electrolysis at 20° C. of an aqueous solution of 4 per cent. borax and 12 per cent. sodium carbonate, applying a current density of 20-30 ampères per sq. dm. at 5-10 volts. Liebknecht (*U.S. Pat.* 128,193) proposes the electrolysis of fairly concentrated aqueous solutions of sodium meta-borate and sodium carbonate, using cathodes of lead or nickel, which are platinum-coated to prevent corrosion. The established electrolytic method now in use for the commercial production of sodium perborate is due to Alsgaard (*Trans. American Electrochem Soc.* 40, 1921). The apparatus is so arranged that the operation is continuous for the electrolysis of a solution containing 4.5 per cent. borax, 13 per cent. sodium bicarbonate, 0.2 per cent. potassium bichromate, and 0.2 per cent. sodium silicate, the density of the current used being 20 ampères per sq. dm. at about 7 volts. Langhard (Assr. to Frederickstad Electrochem. Fabr. A/S, *U.S. Pat.* 1,375,596), has patented an electrolytic process, where a solution of an alkaline borate is electrolysed in the presence of sodium carbonate containing a small percentage of a cyanogen compound. Aschkenasi (*Ger. Pat.* 329,845), proposes the production by an electrolytic method of perborate containing an active oxygen content of 28 per cent. Experience has shown that the product is unstable, much of the oxygen being lost on storage. A stable compound containing 19.5 per cent. available oxygen can, however, be obtained by continued desiccation of the crystallised sodium perborate over phosphorus pentoxide.

Properties and Constitution.

The properties and constitution of sodium perborate have been extensively studied by Bosshard and Zwicky (*Zeitsch. Angew. Chem.*, 1912, XXV. p. 993-999)) and also by Foerster (*Z. Angew. Chem.*, XXXIV., p. 354-355, 1921). The latter brings forward evidence that the perborates are additive, and not substitution products of hydrogen peroxide. Sodium perborate has a high percentage of available oxygen, which is liberated in solution by either acidifying, high dilution, or heat. It is stable in the presence of its water of crystallisation, but decomposition sets in if the water content exceeds that amount. A concentrated solution of hydrogen peroxide—even up to 200 volumes—may be prepared by the solution of sodium perborate crystals in dilute sulphuric acid. With concentrated mineral acids, perborates give ozone. Commercial application has been made of the preparation of peroxide solutions from perborates, the solution obtained being highly pure and very suitable for the bleaching and washing of delicate textile fabrics. As a general oxidising agent, sodium perborate is equivalent to double its weight of hydrogen peroxide. The activity of sodium perborate as an oxidising agent may be shown by the oxidation of chromates and molybdates to perchromates and permolybdates respectively, and in the higher oxidation of proto-oxides.

Uses as a Bleaching Agent.

Sodium perborate has found various applications in several technical industries, and is now a commercial product of considerable technical importance. It is largely used in the textile industry as a bleaching detergent, and enters into the composition of deodorants, germicides, decolourising agents, antiseptics, dentifrices, and various pharmaceutical products. It is used in the determination of bile pigments. Sodium perborate has been found to be a superior bleaching agent in the textile industry, particularly for cleaning whites after the use of logwood black dyes; its superiority lies in the fact that most of the stereotyped bleaching agents tend to lower the strength of the textile material, and this is not the case with perborate. It blends strong bleaching and antiseptic properties, and has been found particularly suitable for cotton goods, and is now in general application at Austrian and German textile factories and laundries. As a detergent it possesses many advantages over sodium peroxide, and has been used effectively as an antiseptic in the treatment of wounds.

Well-crystallised sodium perborate preserves its strength, and is now manufactured on a commercial scale, and many anticipate that it will soon compete successfully with and replace hydrogen and sodium peroxides in the various industries. It has the advantage over hydrogen peroxide of being highly stable, and being a solid it is more easily and economically transported.

Preparation of Metallic Uranium.—R. W. Moore, of the Research Laboratory, General Electric Company, presented before the forty-third meeting of the American Electrochemical Society a procedure for obtaining uranium in a satisfactory condition by means of the action of sodium on the chloride. He gives full description of the method of preparing the chloride, which must be anhydrous, and of using the sodium. The fusion of the reduced metal was accomplished by arc operating in argon at from 50 to 100 atmospheres on a water-cooled table. The metal prepared by this method had the appearance of polished iron, but tarnished when exposed to the air for a few days. It was very ductile.—*Journ. Franklin Inst.*

CHEMISTS AND THE LAW OF CONTRACT.

IMPORTANT PRACTICAL POINTS.

AN interesting and comprehensive lecture on "Some Aspects of the Law of England Affecting Chemists" was delivered by Mr. E. J. MacGillivray, barrister-at-law, before the Institute of Chemistry, in London, on March 9 of this year. Short accounts of the lecture appeared at the time, but the complete text has now been issued in booklet form by the Institute. In view of the importance of certain branches of the subject, we abstract below that part of Mr. MacGillivray's address dealing with the law of contract. The paper was divided into seven parts, the first dealing with the chemist's right to the title of chemist, the second with the charter of the Institute, the third with the chemist's protection in respect of his discoveries, the fourth with the chemist in relation to his contracts, the fifth with the chemist in relation to public health, the sixth with the chemist in relation to public safety, and the last with the chemist in relation to the safeguarding of industries. Dealing with the fourth section of his subject, Mr. MacGillivray said:

Control Over Reports and Certificates.

To the chemist, as to everyone else, the whole law of contract is interesting, but I will not attempt to expound the whole law, or even the general principles of it; I think the most interesting thing I could do would be to take one or two points in the law of contract which might be said more than others to affect you as chemists. It has been suggested to me by your Registrar that it might be interesting if I were to state how the law stands with regard to reports and certificates made by you in the exercise of your profession. This, of course, has special relation to a provision in your by-laws. By-law 57 provides that certain acts shall be deemed to be discreditable within the meaning of section 16 (*c*) of the Charter, and among such discreditable acts is the issue for improper use of reports and certificates. The question thus arises—What is your right in law to control the matter after the report or certificate which you have made has, as a physical thing, left your hands? What right have you got to prevent it being published in your name in a way which you did not contemplate when you made it, and which might discredit you professionally?

Protection by the Law of Libel.

First of all, there is the law of libel, on which you can rely for your protection. It is libellous to publish anything which holds a man up to hatred, ridicule, or contempt. If your report or your certificate is, without your consent, used in such a way as will place upon you the stigma of unprofessional conduct, that would be clearly libellous, and you would have your remedy at law. You could go to the Court and get an injunction to prevent it being used in that way. Of course, it cannot be said that the use of the analysis or certificate of a chemist in connection with any advertisement of any sort is necessarily unprofessional. For instance, take the case of a company prospectus. I can conceive that a formal scientific report of an analyst might quite properly be used in connection with a prospectus, and a chemist might quite properly give such a report for such a purpose, although such a prospectus is, of course, an advertisement. No doubt there are other forms of advertisement of a serious nature, not being "puff" advertisements, in which your certificates might quite properly be used, without any infringement of professional etiquette. At the same time you may not wish your name or your report or certificate to be used in any way at all other than that for which you intended it at the time you made it, so that you must, for your own protection in such cases, look to something other than the law of libel, and it is here that the law of copyright may come in to protect you.

Protection by the Law of Copyright.

When you write a certificate or a report on any analysis or investigation which you have made, you have got copyright in that certificate or report, and *prima facie* you alone have got the right to reproduce the written matter in any form whatsoever. That is your copyright as author, so that, unless you have parted with your copyright or unless you have given some other person a licence to reproduce the written matter, you can stop the reproduction under the law of copyright. In what ways, then, can you part with your copyright? First of all, you part with your copyright if you are employed under a contract of service, and if what you prepare in the way of a certificate or report is prepared for your employer under such contract of service. In such a case the copyright, *ipso facto*, passes to him, and in that way you lose control of it. When there is no contract of service, and you are what is called in law an independent contractor and are employed by someone to make a report or give a certificate, even though you are paid for it, the copyright does not thereby pass to the person who has employed you; the copyright remains with you unless you have assigned it in writing—unless there is something in writing to show that it was intended that the copyright should pass. For example, you may give a report or certificate for the purpose of being used in Court in some legal proceedings. You give it for that purpose only, and you are paid for it. If whoever obtained it and paid you for it were afterwards to use it in connection with some other matter, to publish it as an advertisement in the public press, for instance, you could at once get an injunction to stop that. You may also call in aid the law of contract. You may make it an express term of your contract with the person who employs you that your report or certificate shall not be used except for a specified purpose. As a rule, however, you probably do not have any formal contract, and then you have to rely on one or other of those two branches of the law which I have already indicated—libel and copyright—and they give you quite good protection.

Legal Interpretation of Restraint of Trade.

A very interesting branch of the law of contract, and one which is of special interest to chemists, is that relating to contracts made in restraint of trade. The general principle of the law is that any agreement whatsoever by which a man undertakes not to exercise his trade or calling, whether wholly or partially, or for all time or for a limited time, is *prima facie* void. The law does, however, permit, in the interests of freedom of contract, restraints within limits, but the party to a contract who has imposed a restraint on the free exercise of his trade or profession by the other party, must show that such restraint was reasonably required for his legitimate protection as a contracting party, and, secondly, he must show that the restraint which he seeks to impose is no wider than is reasonably necessary for such protection.

In considering this question of restraint of trade, we have to distinguish very clearly between two different classes of contract. The first are contracts under which a man sells the goodwill of his business. As you know, it is very common, in cases where a man sells his business, for the purchaser of the business to impose upon him a restraint; that is to say, the vendor is restrained from exercising the trade or calling to which the business relates for perhaps a specified time, say five years, or within a specified area. Such a restraint may be absolutely necessary in a contract of that kind. The law, therefore, does permit a restraint of that kind, and any restraint which is reasonably necessary to protect the purchaser and so secure to him the value of what he has paid for is legitimate. But even in the case of the sale of a business, a general restraint prohibiting the vendor of the business from exercising his trade or calling at any place and for the rest of his life would be bad. The question always is whether the restraint which is imposed is reasonably necessary, and no wider than is reasonably necessary for the protection of the purchaser.

Contracts of Service or Apprenticeship.

There is, however, another class of contract—that is, contracts of service or apprenticeship—where you frequently find a clause in restraint of trade. An employee or apprentice may purport to bind himself not to practise or enter other employment after the termination of his service. There the law takes a rather different view of the matter. It will not allow so wide a restraint as it will in the case of a man who sells his business. In the case of a contract of service, the law will not allow an employer to protect himself merely against fair competition by the employee, after he leaves his service. In the case of a contract of service, where an employer attempts to impose a restraint upon his employee in the exercise of his profession after he leaves his business, the purpose of the restraint must be something other than merely to prevent fair competition. It is not lawful for an employer to impose upon an employee a restraint against fair competition, because the law takes the view that that is not in the public interest.

There are certain matters, however, with respect to which an employer is entitled to impose a restraint for his own protection, and the first of these is with regard to his professional or trade connections. An employer is entitled to impose a restraint on his employee in so far as it is reasonably necessary for that purpose. Another thing with regard to which an employer is entitled to protection is in respect of trade secrets. If the restraint is imposed for the purpose of protecting the trade secrets which the employee may acquire in the course of his employment, then, if it is no wider than is reasonably necessary for that purpose, it will be permitted.

Trade Connections and Trade Secrets.

In the case of the employment of a chemist in manufacturing works, I doubt whether, in the great majority of cases, any restraint is permissible on the exercise of his profession after he leaves such employment. With regard to trade connections, restraint for the purpose of protecting the employer's trade connections is not as a rule necessary, because a chemist in manufacturing works is not concerned with the trade connections of his employer. It might be legitimate in the case of a manager who is in charge of a business and who comes into contact with the employer's customers. With regard to trade secrets, it may be that in some cases restraint is permissible for the purpose of protecting the employer's trade secrets, but I doubt if there are many cases where such a clause would be enforced by injunction. The employer would have to show that there were some definite trade secrets of very vital importance to his business, and that the employee had acquired knowledge of these, and that unless an injunction was granted restraining the employee from taking employment in rival works, there would be serious danger of such secrets being divulged. Apart from definite trade secrets an employee is entitled to take away with him and use elsewhere his knowledge of his late employer's methods of business and manufacturing processes. No restraint directed only to prevent that would be permissible. In my opinion the cases are very rare indeed where an employer would be able to get an injunction to enforce a covenant in restraint of trade on the ground that its object was to protect trade secrets. It must be remembered that the restriction, if it is imposed for that purpose, must not be wider than is necessary for the protection of the trade secret which it is designed to protect, and it is very difficult to frame a clause in such cases that is not too wide. For instance, there might be a trade secret which related to a particular class of manufacture; in a soap works, for example, there might be a trade secret which related to the manufacture of a particular class of soap. It might be permissible, if the employee had, in his employment, gained a knowledge of that trade secret, to prevent him, for a period of time after he left the employment, from entering any other soap works which were manufacturing that particular class of soap. I do not think, however, it would be permissible to restrain him generally from taking employment from any soap manufacturer, even within a limited district and for a limited time. You will see, therefore, that it is very seldom, in the case of a chemist engaged in manufacturing works, that a clause in his contract restraining him from entering other similar employment after leaving his employer would be enforced. Most of such clauses are, in my opinion, void, as being in restraint of trade.

Where a chemist is employed as an apprentice or assistant to a professional chemist carrying on a general practice as an analytical and consulting chemist it would no doubt be reasonable, and therefore permissible in law, to restrain him from setting up a similar business on his own account either alone or in partnership within a limited area and for a limited time after leaving such employment, but I doubt whether it would be permissible to extend such restraint so as to prevent him entering the employment in a subordinate capacity of a rival practitioner.

An Important Test Case.

Another question which sometimes arises is whether an employee who has left the service of his employer before its termination, that is to say, who has broken his contract of service, can be restrained by injunction from taking employment with a rival firm before the legal expiration of his period of service. I do not want to say anything which would encourage any of you to break his contract; but there are cases where such a course is morally justifiable. An example of this was the case where a chemist was engaged in certain works on the terms of six months' notice on either side to determine the employment. Business was slack and the employer was cutting down his expenses, and he wished to discharge this particular chemist because the reduced business could not carry the cost of his salary. He therefore gave him six months' notice. The chemist had an opportunity of getting good employment at once with a rival firm. A similar opportunity might not have offered itself at the expiration of six months. The employer took up a dog-in-the-manger attitude and threatened to apply for an injunction to restrain his employee from taking this good job which he was offered. The chemist, as employee, had agreed to give his whole time to his employer's business, and he was undoubtedly contemplating a breach of this agreement by taking other employment before the expiration of the six months' notice. The chemist was advised that the Court would not grant an injunction restraining him from doing so, and in pursuance of that advice he took the good job which was offered, and his late employer did not carry out his threat of taking proceedings.

The principle which the Court applies in such cases is that it will not by its order compel a man to work for any particular employer, and it will not by granting an injunction compel him, as an alternative, to remain idle. If a contract of service is broken by an employee the employer's proper remedy is an action for damages if he has suffered any by, for instance, having to employ another man at a higher salary; but in this particular case it was obvious that there was no pecuniary damage suffered by the employer, as his reason for discharging the chemist was that he had not sufficient work for him to do, and could not afford the salary. The case might have been different if the chemist had in his contract of service with his first employer entered into an express negative covenant not to work for anyone else during the period of his service. There have been cases where the Court has enforced such an express negative covenant by restraining the employee from taking employment elsewhere. Considerable doubt, however, has been thrown on the legal position with regard to this. In the present state of the authorities a Court of first instance at any rate would probably feel bound by the authority of the earlier decisions to grant an injunction where there was an express negative covenant, but I am inclined to the opinion that the House of Lords, if the question came before them at the present day, would take a broader view and refuse an injunction even in such a case where the effect of an injunction would be to compel a man either to perform specifically his contract to render personal service to a particular employer or to remain idle. The tendency would be to regard the granting of such an injunction as contrary to public policy in that the services of a skilled man might thus be lost to the detriment of the national interest.

Arbitration Clauses in Contracts.

While dealing with the chemist in relation to his contracts I should also like to mention the subject of arbitration. There are different kinds of arbitration clauses: you can have an arbitration clause which merely refers, or rather is an agreement to refer, any dispute which may arise under the contract to arbitration, or you may go further and have not only an agreement to refer to arbitration, but also a condition that reference to arbitration and the award of the arbitrator shall be a condition precedent to any action brought in connection with the contract.

No arbitration clause, however, can altogether oust the jurisdiction of the Courts. If you have an arbitration clause which is merely an agreement to refer disputes to an arbitrator, it is always open to either party to the contract to commence an action, and the remedy of the other party, if he wishes to enforce the agreement to arbitrate, is to apply to the Court to stay the proceedings in the action so that the matter may be referred to an arbitrator according to the terms of the arbitration clause. But although a party may apply for a stay, it does not follow that the Court will grant one. As a general rule, if fraud is alleged by one party against the other, the Court will not grant a stay, because the Court considers that allegations of fraud are so serious, as affecting the honour and reputation of the party charged with fraud, that the Court itself ought to deal with them. Another class of case where the Court may refuse to stay the action and to refer the matter to arbitration is where the main issue raised in the dispute is an important and difficult question of law.

If the award of an arbitrator is made a condition precedent to the bringing of any action on the contract, then a party may be compelled to go to arbitration in the first instance, because if either party were to bring an action in the Courts without first having obtained the award of an arbitrator in his favour, the arbitration clause would not merely be a good ground for the other party applying to the Court to stay the action, but it would afford a complete defence to the action. The dispute, however, must be one arising solely on the contract itself, and if one party repudiates the contract altogether, for instance, on the ground that it was induced by fraud or even by innocent misrepresentation, then it is open to the other party who maintains the validity of the contract and claims under it to disregard the arbitration clause and bring his action in the Courts. His opponent, having repudiated the contract altogether, cannot at the same time set up as a defence to the action the arbitration clause, which is part of the contract which he has repudiated.

But even after a dispute comes before an arbitrator the Courts still have jurisdiction in respect of all questions of law which may arise in the course of the arbitration. The decision of the arbitrator, provided he conducts the arbitration properly, is final on all questions of fact, but either party is entitled to go from the arbitrator to the Court on any question of law. An agreement that neither party shall require the arbitrator to state a case for the opinion of the Court, or apply to the Court to direct the arbitrator to state a case, is void as against public policy. If nothing is said in the arbitration clause as to the nomination of an arbitrator, then under the Arbitration Act the reference will be deemed to be to a single arbitrator to be agreed on by the parties when the dispute arises, or in default of agreement to be nominated by the Court. If the agreement in the arbitration clause is to refer disputes to two arbitrators, one to be chosen by either party, the two arbitrators when so chosen may appoint an umpire, as without an umpire there might be, and usually would be, a deadlock. On the whole a reference to a single arbitrator is the most satisfactory and the cheapest. When the reference is to two arbitrators, one to be appointed by each party, and one party appoints his arbitrator and the other party refuses or delays unreasonably in appointing his arbitrator, the arbitrator appointed by the one party may proceed with the reference as if he were the sole arbitrator.

THE MARKETS FOR OILS AND FATS.*

REVIEW OF 1922 AND FORECAST FOR 1923.

IT may be taken as an unalterable economic law that the cycle in which trade moves consists of four phases, viz.:

1st Phase.—A prolonged period of general dullness, which might be described as the period of convalescence after the slump, sellers slowly liquidating the remnants of purchases made during the last boom, and buyers confining themselves to purchases to cover their immediate requirements. As a result of this policy less and less capital is required to carry on trade, with the result that discount rates are reduced and we are automatically carried into the

2nd Phase—when the money released by trade flows to the Stock Exchange, producing an all-round improvement in stock markets. At the same time cheap money assists to re-establish the general confidence, and we are unconsciously carried into the

3rd Phase—when, assisted by low rates of interest, the tendency gradually springs up to cover requirements further ahead, thus producing a wave of all-round buying which generally tends to be exaggerated and to develop into a boom which inevitably develops into the

4th Phase—the period of the slump and which, as a rule, comes practically without any warning. It is the period of reaction after the fever, and its intensity depends on the extent to which prices during the boom have been driven up without justification.

The Four Phases of the Trade Cycle.

The first indication that the tide is turning is generally found in an advance in money rates with an attendant drop in values on the Stock Exchange, and sometimes a restriction of credit by the banks, accentuating thereby the process of the rapid liquidation. When this movement has more or less spent itself, and prices have settled down to a reasonable level, we again pass into Phase 1, in which position we find the markets during the period under review, namely, the year 1922.

The year opened at a time when the 1920-1921 slump had spent itself, and the whole year was noted for a general disinclination to take a view any distance ahead, traders all over the world mainly confining their efforts to setting their houses in order after the upheavals through which trade had passed during the preceding six years. Consumers throughout the year lived from hand to mouth, and, on the whole, this policy paid them well, as sellers could nearly always be found of material on the spot or available for early delivery at a discount under prices quoted for later delivery. Consumers who, for a considerable time, had followed a hand-to-mouth policy, found themselves compelled to be in the market continually as buyers, and we were thus steadily getting ready for an improvement in markets which was bound to set in as soon as offers for early delivery became scarcer. Markets towards the end of the year were, therefore, in a distinctly healthy position. Prices were low, consumers had only covered their immediate requirements, and old stocks had gradually passed into consumption. Dealers were still shy after their 1920 and 1921 experiences, and probaby had smaller commitments on their books than usual. It is hardly surprising, therefore, that a steady improvement set in towards the end of the year.

General Trend of Prices.

Generally speaking, the prices of oils and fats during the year have been distinctly low, when compared with other commodities. The trade index figure shows the average figure for the year was 55 per cent. above the July, 1914, figure, and taking the average value of Straits copra just before the war at £26 to £28 per ton, palm kernels at £20 to £21, and good mixed tallow at £36 to £38 per ton, the average figure for these three articles, if brought into line with other commodities, viz., 55 per cent. above pre-war prices, would give us £40 to £43 for copra, £31 to £33 for palm kernels, £56 to £59 for tallow, whereas we find that Straits copra actually stood at £23 2s. 6d. in September, 1922, palm kernels at £16 10s. in September, 1922, and good mixed tallow at £38 10s. in May, 1922. The only notable exception was linseed oil, which rose to £44 15s. in May, 1922, against £24 in July, 1914, and this was due entirely to strong American buying on the expectation of the new Tariff coming in, which put an end to conditions ruling under the Fordney Emergency Tariff, introduced in 1921, by which the duty on linseed oil remained at 10 cents per gallon, whereas linseed was put up to 30 cents per bushel. There is no doubt that the U.S.A. markets have, during 1922, played a more important rôle in the world's oil and fat markets than at any other time, and the tendency is for the rôle to increase in importance.

America the Predominant Factor in the Market.

The slump in the U.S.A. was probably more severe than anywhere else, but the U.S.A. markets recovered more quickly, which, in view of their enormous wealth, is hardly surprising. Trade in America was showing distinct signs of recovery early in the summer, but the improvement was retarded by various strikes, principally the railroad strike. Once their labour troubles were settled a quick improvement set in, and has been maintained ever since, and the introduction of the new Tariff which, after various delays, finally materialised in September last, and whereby the import duties all round were heavily increased, had the natural effect of advancing all prices in the U.S.A. very considerably, with the result that a fresh inflation, which might almost be termed a boom, was started and is still continuing at the present time. To what extent the country will ultimately benefit economically by this increase in prices is a problem which we must leave to the political economists to settle. So far as oils and fats are concerned, the fresh duties imposed were as given in the table below.

A most interesting position was thereby created. We may say that last summer the whole position of the world's oil and fat markets hinged very largely on American cotton oil. We have seen in previous years, when we had a normal crop of 12/13,000,000 bales of cotton, that the U.S.A. have always exported from 50,000 to 160,000 tons of oil. The 1921-22 crop, which was abnormally small, viz., below 8,000,000 bales, only produced sufficient cottonseed oil for

* Messrs. Thornett and Fehr, of Baltic House, Leadenhall Street, London, E.C. 3, have just published their "Review of the Oil and Fat Markets for 1922." In view of the considerable trade interest of their observations, we are printing above the greater part of the introductory chapter to the "Review."

Tariff Rates in the United States of America.

	Old Tariff. (before 28/5/21).	Emergency Tariff (from 28/5/21 to 21/9/22).	Present Tariff (from 21/9/22).
Copra	Free	—	
Palm kernels	Free	—	
Rape seed	Free	—	
Sesame seed	20 cents per bushel	—	Free
Palm oil	Free	—	
Palm kernel oil	Free	—	
Sesame oil	1 cent per lb.	—	
Castor oil	1⅜ cents per lb.	Unchanged	3 cents per lb.
Linseed oil	1¼ cents per lb.	Unchanged	3¾ cents per lb.
Rape seed oil	1¼ cents per lb.	Unchanged	Unchanged
Cocoanut oil	Free	2⅝ cents per lb.	2 cents per lb.
Cotton seed oil	Free	2⅝ cents per lb.	3 cents per lb.
Groundnut oil	6 cents per gal.	26 cents per gal.	30 cents per gal.
Soya bean oil	Free	2⅝ cents per lb.	2½ cents per lb.
Groundnuts undec.	1¼ cents per lb.	3 cents per lb.	3 cents. per lb.
Groundnuts, dec.	¾ cents per lb.	Unchanged	4 cents per lb.
Castor seed	¼ cent per lb.	Unchanged	½ cent per lb.
Flax seed	20 cents per bushel	30 cents per bushel	40 cents per bushel.
Soya beans	Free	Free	½ cent per lb.
Cottonseed	Free	Free	⅛ cent per lb.
Tallow	Free	—	½ cent. per lb.
Oleo oil	—	—	1 cent per lb.
Oleo stearine	Free	—	1 cent per lb.
Oleo margarine	2½ cents per lb.	—	8 cents per lb.
Butter	2½ cents per lb.	—	8 cents per lb.
Whale oil	5 cents per gal.	Unchanged	6 cents per gal.
Fish oils	3 cents per gal.	Unchanged	20% *ad valorem*.

American requirements, with a margin for export of only 33,620 tons, the bulk of which went to Canada and Central and South America. In the summer of 1922, when it was known that 1922-23 cotton crop would amount to 8,500,000-9,000,000 bales, the problem to be solved was whether the U.S.A. would again be able to consume the whole of the resultant cotton oil or whether there would be an appreciable surplus available for export. In the latter case the price of oil, which fluctuated around 8 cents per lb. in New York in August, 1922, would obviously have to go down, as Europe was not in a position to absorb any oil at that figure. On the other hand, if the American consumption was sufficiently big to absorb the whole of the crop, the price of 8 cents per lb. was undoubtedly too low, and we now see that this has actually been the position, for, as a result of the high Tariff wall built up against soya bean oil, combined with a poor peanut crop in the U.S.A., no surplus of cotton oil for export to Europe was available, and the price actually passed 10 cents for refined oil in December, 1922. Europe, therefore, had to satisfy its requirements in liquid edible oils with soya bean oil, groundnut oil and sesame oil.

A remarkable feature of the year 1922 was the general world shortage of liquid oils. The 1921-22 olive oil crop and cotton oil crop could almost be termed failures, whereas the linseed crop was also well below the average, and yet, notwithstanding the fact that the principal oil-producing crops were so very short, prices for oils and fats generally were distinctly low, and, in some cases, for instance copra and palm kernels, the lowest post-war record was established. There is no doubt that the general economical position has been slowly improving throughout the year, and, at the time of writing, we find distinct indications that we are slowly passing from the first phase to the second phase of the usual trade cycle. Exchanges, generally, have been fluctuating wildly throughout the year. Marks stood at 795 to the £ in January, 1922, and at 33,000 to the £ in December, 1922. A few years ago we would have thought that trade in these circumstances would come to an entire standstill, but, on the contrary, we find that, during the past year, the German import trade has not been very greatly affected by exchange fluctuations. Apparently the Germans find no difficulty in adjusting the prices in the interior very rapidly to the fluctuations of their exchange. This is borne out by the Trade Index Figure of the principal articles. The German figure stood at 205.417 per cent. in December, 1922, based on 100 per cent. in 1913, and, taking into account the depreciation in the exchange, reduced to a gold basis, prices have appreciated about the same as elsewhere, that is to say, from 40 per cent. to 50 per cent.

Position in the European Markets.

The margarine industry in the United Kingdom has, generally speaking, not been very profitable, due mainly to the price of standard margarine having been maintained steadily at 6d. per lb., which only shows a return on the cheapest raw material prices of the year. On the other hand, margarine makers seem to have been successful in increasing the sale of their higher grades, which is more profitable. The soap industry in the U.K. has been flourishing, and it has even been possible again to increase the exports somewhat. An interesting proof that there has been little competition in the soap trade as opposed to the margarine trade is to be found in the fact that it has been possible to maintain the price of soap over that of the low-grade margarine.

Figures of the imports and exports of oils, fats, and oilseeds into and from the U.K. during the year 1922, as compared with the previous two years, are well worth studying closely. The total net imports, excluding butter, margarine, and lard, arrived at by deducting the exports from the imports, amount to 480,371 tons in 1922, as against 473,959 tons in 1921 and 558,964 tons in 1920, and, including butter, margarine, and lard, to 838,007 tons in 1922, as against 807,494 tons in 1921 and 752,597 tons in 1920. We see, therefore, that, so far as the U.K. is concerned, supplies have been well in excess of the previous two years, indicating a steady increase in the demand. There has been a very large increase in the imports of butter, which reached the figure of 213,428 tons in 1922, and which is up to the average imports of the years just preceding the war.

As regards imports to the U.S.A. for 1922, the figures which are most striking are those for linseed oil, amounting to 64,347 tons, and palm oil amounting to 25,677 tons, both of which establish a record considerably in excess of any previous year's import. For the first time we notice that cotton seed figures among the import articles, the imports for 1922 being 17,761 tons. As regards the exports from the U.S.A., what strikes us first are the cotton oil exports, which amounted to only 33,620 tons, and are far and away the smallest on record. The lard exports have again been on a heavy scale, viz., 342,375 tons, a figure which was only surpassed by the 1921 exports, which amounted to 387,916 tons.

Dutch exports again show a further increase in the export of cocoanut oil, which no doubt consists principally of refined cocoanut oil exported to Germany. The margarine exports are somewhat smaller, and amount to 47,330 tons. We now seem to have reverted to the pre-war position, when practically the whole of the Dutch margarine exports went to the U.K. In recent years Holland has been shipping margarine on a fairly large scale to Germany, but apparently the German margarine manufacturing capacity is again sufficient for home requirements. It is quite clear that the German crushing industry, notwithstanding the fluctuations in the exchange, is again gradually getting into its stride. Generally speaking, there is a considerable increase in the quantities of seed imported. We see, for instance, that in rape seed 106,301 tons were imported during May-December, 1922, as against 15,695 tons during May-December, 1921. The palm kernel imports for May-December, 1922, amounted to 95,477 tons, and for the whole year 126,880 tons, and the copra imports during May-December, 1922, amounted to 206.574 tons, and for the whole year to 282,676 tons. The oil imports, generally speaking, show a decrease with the exception of fish oil and whale oil, of which 62,621 tons were imported into Germany last year. The margarine imports for the year have dropped to 359 tons.

The Present Outlook.

As regards the present outlook it is clear that we cannot really say that there is any shortage of supplies, and the general advance in prices which we are experiencing at the present time can only be attributed to a general adjustment of oils and fats prices to those of other commodities. The principal factors which, in our opinion, will influence the course of markets during 1923 are:— (1) The economic position of the U.S.A. generally. (2) Any important fluctuations taking place in the general commodity Index Figure. (3) The Chicago lard situation. (4) The estimates of the American cotton crop, and especially whether the U.S.A. will again be able to consume their own cotton oil or whether they will have to export an appreciable surplus oil to Europe. (5) The position of the butter market; and (6) The world's linseed crops. These, we think, are the factors which will mainly shape the course of the markets, and their development should, therefore, be closely watched, as they may give us some warning of impending movements.

Another factor which would naturally affect markets is any serious complication in the European political situation, but it is never possible to gauge the effect of political trouble on the markets beforehand. All we know is that, in case of serious political trouble, markets are sure to be affected, but in which direction no one can possibly estimate until we see how matters develop.

PYRITES TRADE PROSPECTS.

PROPOSED PRODUCERS' COMBINE.

COMMENTING upon the agreement between the producers of pyrites, which although not yet signed is almost certain to materialise and which has already led to a general increase in prices of ten shillings per ton, Pierre Bancigny, writing in *Le Phosphate et Les Engrais Chimiques*, states:

The large producers such as the Rio Tinto which can deal with 2 to 3 million tons of pyrites per annum, the Tharsis Company which has now an annual productive capacity of a million tons, but which in 1922 only produced 220,000 tons, the Huelva Company which sold 300,000 tons of pyrites in 1922 as compared with 263,000 tons in 1921, the Pena Copper Company with 100,000 tons, San Platon with 40,000 tons, Campanario with 35,000 tons and Montecatini with 400,000 tons would by now have arrived at complete agreement, if the offers made to the producers of less importance as to their share in the markets had been accepted.

The Position of the Tharsis Company.

Another factor, which if rumour is to be relied upon, has operated against the conclusion of the formal agreement is the attitude adopted by the Tharsis Company, who claim that in their case it is unfair, in fixing the amount of pyrites that the individual producer may sell under the agreement, to take their present production as the basis. It must be admitted that within recent years the Tharsis Company has developed appreciably its possibilities. Only a short time ago it was thought that the pyrites reserves of the Company were approaching the point of exhaustion, but the systematic developmental and prospecting work of the Company has indicated the existence of huge unsuspected reserves, particularly in the neighbourhood of Tharsis and Calanas. So far back as the general meeting of shareholders of the Tharsis Company in 1921, the chairman intimated the probable results of these developments. Two new lodes have been discovered, the one at Calanas equalling in thickness that of the Perrunal deposit belonging to the Huelva firm.

The Tharsis Company realising the immense potentialities of its new reserves has adopted a vigorous developmental policy and erected a new block of factory buildings. It has also improved its transport system and built a new loading quay to cope with the anticipated larger output. A production of 5 to 6 times the present amount is anticipated within a few years and the company, quite naturally, demurred at being valued at present figures.

The other producers on their part, cannot be blamed, when the narrowness of the present day market for pyrites is taken into consideration, for refusing to allow the quota of the Tharsis Company to be assessed on a principle fundamentally different from that applied to the other companies. At one time, owing to this real difficulty, the negotiations had every appearance of dropping through altogether, but the insistent pressure of the competition of American sulphur has compelled some sort of an agreement to be made.

At present the world's productive capacity for pyrites is five million tons per annum. The production of American sulphur has grown from 250,000 tons in 1910 to 1,250,000 tons in 1920, with exports to Europe, which were nil before the war rising to a present figure of 500,000 tons per annum. For the past two years not more than two and a half million tons of pyrites per annum have been required by the chemical industry, and prices have been cut to such an extent that the margin of profit has been practically eliminated.

THE PLATINUM INDUSTRY OF COLOMBIA.

WORLD'S PRESENT LARGEST PRODUCER.

PLATINUM is distributed widely in Colombia, but is found mainly in the rivers Atrato, San Juan, Condoto, Opogodó, and their affluents in the Chocó region, and also in the region of Barbacoas, on the Pacific side. In the absence of Russia, this region is the largest exporter of platinum in the world. The Condoto river is to-day the centre of the platinum industry. The recent prospecting in the river Patia is expected to give very satisfactory results. Several companies are now dredging with very promising results.

The platinum exported during 1922 was valued at £3,000,000. The richest known platinum region in Colombia (and as far as is at present known in the world) lies in the now famous Chocó district—the metal being recovered from the head waters of the Atrato river, also from the San Juan river and its tributaries, the chief of which being the Condoto river. In the Condoto river district platinum predominates over gold in the alluvial ground, the percentage of the former being about 96 per cent. of the two mixed metals; whilst in the Atrato (Quibdo) deposits gold predominates, the platinum content being only from 10 to 15 per cent. of the combined metals.

The platinum recovered in Colombia has generally been obtained from the sand and gravels of present stream channels. Careful investigation in recent years has proved the existence of platinum-gold alluvial deposits covering a total area of more than 5,000 square miles, many of those in the Chocó district being suitable for dredging and others for hydraulising. In 1915 it was estimated that the reserves of gravel in the productive areas held by British and American companies amounted to 336 million cubic yards, of which 68 million cubic yards could be considered as proved ground capable of being worked at a profit under the conditions then existing—since 1915 the estimated reserves have been largely increased and the working conditions also much improved.

Although platinum is found quite abundantly in the beds of present Colombian rivers, it is also said to occur there in a conglomerate of the Tertiary age, which appears to have been laid down in a basin whose upper surface is now about 1,600 feet above sea level. Platinum is found in the rivers only where this conglomerate has been eroded, their beds being barren of the metal above the areas underlain by that formation; the stream or river deposits are re-concentrations from the older gravels.

The total production of platinum in Colombia since 1778 has been estimated at more than 700,000oz. Most of the platinum recovery has been obtained irregularly by crude native methods (ground-sluicing and panning), but in recent years British and American capital has been attracted to the platinum region, and dredging-plants operated by steam-power or (as in the case of the No. 2 dredge of the South American Gold and Platinum Corporation) by internal combustion engines have been installed in such localities as are suitable for exploitation by that method. It is to the adoption of dredging that the Colombian industry owes its recent progress and its promising outlook. The Chocó district has shown a steadily increasing output of platinum in recent years, rising from about 10,000 crude oz. in 1910, and 12,000 crude oz. in 1911 and 1912, to about 35,000 crude oz. in 1920.—*The Colombian Trade Review.*

CORRESPONDENCE.

THE COLOURING OF POISONS.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—In the interests of public safety it will be unfortunate if a recent decision of the General Medical Council be accepted as the final word in the highly important question of colouring deadly poisons. The facts are simple. After careful experimenting by British dyemakers and pharmacists the Pharmaceutical Society of Great Britain recommended brilliant green to the Privy Council as a colouring for a preparation of strychnine. The Privy Council forwarded the suggestion to the General Medical Council, as the body who could say whether brilliant green would interfere with the healing properties of the strychnine preparation in question. Thereupon the General Medical Council unanimously condemned the proposal, and that for six reasons, only two of which can be said to have a remote connection with the curative aspect of the question—namely, that in certain mixtures brilliant green undergoes colour changes which "might be objectionable" to patients, and that a coloured solution "would be objectionable" for hypodermic injection.

The four other points made were: (1) That it was only proposed to colour one strychnine preparation; (2) that risk would arise from keeping coloured solutions side by side with uncoloured; (3) that the preparation being uncoloured in other countries, difficulties of an international kind would arise; and (4) that the question was a general one, and should not be determined in the case of a single preparation of a single poison. These four objections may be just, or they may not. What I do submit is that they are matters of policy to be determined by Parliament in open debate, rather than settled autocratically by the most conservative of our trade unions.—Yours, etc. James Sexton, M.P.

House of Commons, S.W. 1, July 16, 1923.

ITEMS OF INTEREST.

Obituary.—We regret to announce the death, at the age of 63, of Sir Robert Park Lyle, Bt., chairman of Tate and Lyle, Limited, sugar refiners, which occurred on Wednesday last week.

Gas Prices Reduced.—It is announced that the Gas Light and Coke Company have reduced their charges for gas from 9.2d. to 8.6d. per therm.

British Empire Exhibition.—It is officially announced that the Prince of Wales has consented to become president of the British Empire Exhibition. His Royal Highness has hitherto been president of the general committee.

American Cellulose Developments.—Preparations are being made for the issue of more capital for the American Cellulose and Chemical Manufacturing Company, whose debentures were placed in this market some time ago.

Trade Agreement with Czecho Slovakia.—On Saturday, July 14, a commercial treaty, based on the principle of the most-favoured nation, was signed by Lord Curzon on behalf of this country and by Dr. Benes on the part of Czecho Slovakia.

American Butyl Alcohol Production.—It is announced that the Commercial Solvents Co. has bought the plant of the United States Food Products Co., at Peoria, Ill., to be remodelled and used for butyl alcohol manufacture. The U.S. demand for butyl alcohol or "butanol" as it is now usually termed there, is growing rapidly.

Literary Intelligence.—Volume II., Part II., of Molinari's Organic Chemistry will shortly be ready. This volume completes the Organic Section of the work, thus making available a comprehensive treatise covering the whole ground of industrial chemistry, both inorganic and organic. The publishers are Messrs. J. and A. Churchill.

New Companies in 1923.—During the first half of this year 4,247 new companies were registered at Somerset House—or 207 more than for the corresponding half of 1922—of which 239 were public and 4,008 private, states a report issued by Messrs. Jordan and Sons. The total amount of capital involved was £67,307,328., as compared with £65,087,216. last year.

Magadi Soda Reconstruction.—The board of the Magadi Soda Company announce that arrangements for a reconstruction scheme are now well advanced, but are subject to certain assents which, it is feared, cannot be obtained before the long vacation. It is hoped to have everything in order when the Courts reassemble in October. The reconstruction scheme cannot be circulated pending the completion of certain negotiations with the Government.

Oil-refining by Silica-gel.—The Standard Oil Co., of Indiana states that the company does not contemplate taking over the silica-gel process of refining gasoline. It is further stated that some time ago the process was looked into, but the results obtained did not seem to warrant the purchase of the rights to use the process. The Standard plants are equipped with the improved Burton stills, and the results obtained are said to be very satisfactory.

Pig-iron Production Decreasing.—The production of pig-iron in the United Kingdom in June amounted to 692,900 tons, compared with 714,200 tons in May, and 369,200 tons in June, 1922. The furnaces in blast at the end of the month numbered 222, four having been blown in and five having gone out of blast during the month. The production includes 246,700 tons of hematite, 215,200 tons of basic, 146,500 tons of foundry, and 41,600 tons of forge pig-iron.

Official Report on Oil-heater Explosion.—The official report has been issued of Mr. R. W. Gunston, of the Board of Trade, as the result of the inquiry into the explosion from an oil pre-heater at a colliery by-products works at Wombwell. Since the explosion, states the report, a new pre-heater of similar design, and by the same makers, has been installed. All cocks have been removed from the oil line, and the two pre-heaters are now permanently in series. The safety valves have been removed from the top covers, and one is now fitted on the pump delivery pipe, where it comes in contact with cold oil, and is not so liable to gum. It is also fitted with a smaller weight than previously. In this new position it is under the more immediate notice of the still-room attendant, and an oil pressure gauge is fitted alongside it.

Coal Output.—The output of coal for the week ended July 7 was 5,305,800 tons, compared with 5,400,700 tons in the preceding week and 4,597,800 tons a year ago.

German Zinc Smelting Association.—According to the *Kolnische Zeitung*, the Zinc Smelting Association has decided to prolong its activites until the end of the year.

American Wool-scouring Laboratory.—It is reported that the United States Department of Agriculture have completed plans for the establishment of a wool-scouring laboratory.

Change of Address.—The London offices of the United States Department of Commerce have been moved from the neighbourhood of the American Embassy in Grosvenor Gardens to Bush House, Aldwych.

Absent Debtor's Examination Adjourned.—At the public examination of William W. Coe, jun., chemical manufacturer, of 24-26, Holborn, it was stated by the Official Receiver that the debtor had not surrendered and was believed to be in New York. The examination was adjourned *sine die*.

Institution of Electrical Engineers.—The result of the ballot for the election of new members of the council of the Institution of Electrical Engineers, for the session 1923-24, is as follows:—President, Dr. A. Russell; vice-president, Sir James Devonshire; hon. treasurer, P. D. Tuckett.

Ironstone Miners' Wages.—Negotiations at Middlesbrough yesterday between Cleveland mineowners and the miners' executive resulted in an agreement for a 14 per cent. advance for the Cleveland ironstone miners, to date from Monday next. The wages will be 102½ per cent. above the standard.

Freights to South Africa.—It is officially announced that where cement and superphosphates are carried from European to South African ports under 17s. 6d. a ton of 2,240lb. for superphosphates, and of 2,000lb. for cement (gross weight), a dumping freight duty will be imposed equivalent to the difference between 17s. 6d. and the frieght charged. The duty will become immediately effective.

Price of Motor Spirit Reduced.—From Thursday, July 19, there has been a further reduction made in the price of motor spirit and refined oils. The reduction amounts to 3½d. per gallon in the case of motor spirit, which now makes the price of No. 1, in tins, 1s. 8½d. per gallon, against the old price of 2s. The price of No. 3 grade spirit will be 1s. 6½d., against the old price of 1s. 10d. per gallon. Refined lubricating oil is reduced by a penny per gallon.

Poisoning Fatality in Metal Foundry.—At the inquest held on Saturday last on E. George Wright, a labourer employed at Fry's Metal Foundry, Holland Street, Southwark, it was thought by the police divisional surgeon that death was due to poisoning by arseniuretted hydrogen. He had preserved certain organs with a view to analysis. Mr. Alfred Munday, chief metallurgist and London manager at Fry's Metal Foundry, said he could not account for the arsenic being evolved, if it caused Wright's death. The inquest was adjourned.

University News.—At a meeting of the Leeds University Court, held on Wednesday, the regulations for the degree of Master of Science were modified considerably. Whereas up to the present it has been possible for Bachelors of Science graduated at the University with honours to be awarded the M.Sc. degree without further examination, from October 1, 1923, candidates for the M.Sc. degree will be required to prosecute research, present a thesis on the research, and, if required, to submit themselves for examination. This new degree ordinance rectifies an anomaly and places Leeds in uniformity with most University centres.

Personal.—The Court of the Salters' Company has appointed Professor Arthur Smithells to be director of the Salters' Institute of Industrial Chemistry.—Mr. Wm. Smith has been appointed agricultural adviser to the Potash Syndicate for the Border and Northern English counties.—Mr. L. M. Clark, of Sidney Sussex College, Cambridge, has been elected by the College to a research scholarship in chemistry of the value of £150.—The retirement of Mr. Thomas Clarkson, chief accountant of the United Alkali Company, has been marked by the presentation of a silver tea and coffee service from his colleagues. The presentation was made by Sir Max Muspratt, who said Mr. Clarkson had been chief accountant since the company's formation in 1891. He is now succeeded by Mr. T. Whinyates.

Potash Feldspar in Ontario.—Five miles from Perth, in Lanark County, Eastern Ontario, a deposit of high potash feldspar has been discovered. Operations to date have been confined to a dyke of feldspar 1,000ft. long and 300ft. wide. This dyke contains many thousands of tons of marketable feldspar, sufficient to supply the ceramic industry of America for a long time. Samples tested by a large manufacturer of insulators have been reported upon as being satisfactory.

Petroleum Bill Report.—The House of Lords Committee on the Petroleum Bill state that they consider that a new Bill should be introduced to amend and improve the existing law. In such a revision opportunity would be offered to bring every aspect of the whole petroleum industry under the Petroleum Department of the Board of Trade. The present Bill was therefore reported without amendment.

British Engineering Standards Association.—The fifth annual general meeting was held in London on Thursday, July 12. The Chairman, Sir Archibald Denny, Bart., in reviewing the year's work, laid stress on the fact that the Association was faced with a deficit of some £1,700. and he hoped that both His Majesty's Government, as well as industry as a whole, would assist in putting the finances of the Association on a more stable basis.

New Benzol Plant in Canada.—The Ford Motor Co., of Canada, is constructing at its works at Walkerville, Ontario, a by-product coking plant, primarily for the purpose of producing benzol for motor fuel. The plant will cost about $500,000, and its capacity will be 400 tons of coal a day. It is understood that if this plant is successful in operation the Ford interests will erect a number in different localities.

Tariff Notes.—As from July 4, inorganic acids from all countries are admitted into New Zealand duty-free. The duties on crude oils and greases are suspended. From September 16 empty glass bottles and glass jars will be subject to preferential duties at 20 per cent., and general duties at 35 per cent. *ad val.*—In the proposed new Finnish tariff it is anticipated that there will be a reduction in the import duties on salt, caustic soda, and bleaching powder. The duty on cement is expected to be increased.

Institution of Civil Engineers.—At the annual conversazione of the Institution of Civil Engineers, held at Westminster on Thursday of last week, Professor Sir George Scott Moncrieff demonstrated an emulsion that has been tried with great success on the roads in eliminating dust, and expressed the hope that the method might prove equally successful in eliminating the coaldust that is so fatal a cause of catastrophe in coalmines. Professor Hele-Shaw produced on an engineering scale the stream line filters that he showed some months ago at the Royal Society.

Injunction Against Oil Refiners.—In the Chancery Division last week Mr. Justice P. O. Lawrence made an order for the release of Charles Wm. Kendall and his brother Charlie, committed to prison for contempt of Court upon the application of C. T. Bowring and Co., Ltd., of Grimsby. Messrs. Bowring and Co. had obtained an injunction to restrain Charles Wm. Kendall from being concerned in the business of fish or whale oil extraction within 100 miles of Grimsby. His lordship held that Charles Wm. Kendall was concerned in a business at Pyewipe, which, he said, he had sold to his brother Charlie, and Charles Wm. Kendall was accordingly committed for contempt of Court, and his brother Charlie for aiding and abetting him. Mr. Baines (for C. T. Bowring and Co.) said there were negotiations afoot to enable the Kendalls to carry on business at Gildersome.

Ramsay Memorial Fellowships.—The Ramsay Memorial Fellowship Trustees announce the following elections to Fellowships and renewals of Fellowships for the Session 1923-24:—A British Fellowship of £300. to Mr. Samuel Coffey, M.Sc. Ph.D. A British Fellowship of £300. to Mr. Alan Francis Titley, B.Sc., D.Phil. A British Fellowship of £300. renewed to Dr. R. W. Lunt, B.Sc., M.Sc., Ph.D. A Glasgow Fellowship of £300. to Mr. Thomas S. Stevens, B.Sc. A Glasgow Fellowship of £300. renewed to Mr. J. A. Mair. A Norwegian Fellowship of 5,400 kroner to Mr. Gunnar Weidsmann, to work at Cambridge under Professor Gowland Hopkins. A French Fellowship of the value of £100., plus 14,000f., to Dr. H Weiss, of La Sorbonne, who will work under Professor Sir William Bragg at the Royal Institution (Davy Faraday Laboratory). A Netherlands Fellowship of £300. to Mr. J. Kalff, doctorandus in chemistry of Amsterdam. A Danish Fellowship of £300. to Mr. Kristian Hjandahl. Appointments to the Canadian, Greek, Italian, and Swedish Fellowships will be announced shortly.

OUR BOOKSHELF.

Second Year College Chemistry. By William H. Chapin, Associate Professor of Chemistry in Oberlin College, Ohio. London: Messrs. Chapman and Hall, 11, Henrietta Street, Covent Garden, W.C. 2; price, 15s. net.

A very useful text book which teaches the student to think for himself, and to realise that the chemistry of to-day is a rapidly-growing science. Although modelled on an American University course the work should meet with a favourable reception from all teachers of chemistry, who believe that a thorough grasp of fundamental principles rather than the accumulation of a mass of details is the goal to be aimed at in their work. Starting with the kinetic theory, the book deals with the gas laws, the laws governing change of state, Avogadro's law and molecular weights, the quantitative laws of chemical combination, the atomic hypothesis and atomic weights, equations and chemical valency. The periodic system which is next discussed is followed immediately by chapters in the most modern developments in radioactivity and atomic structure. After physical chemical considerations of solution and osmotic pressure have been examined the theory of ionisation and chemical indicators are discussed. Chapters on homogeneous, heterogeneous and complex equilibria and electrochemistry, complete a volume, the contents of which we have but imperfectly described. The exercises at the end of the chapters strike us as being particularly excellent, and we can confidently recommend the work to English teachers and students.

Second Year College Chemistry (A Manual of Laboratory Exercises.—By William H. Chapin. London: Messrs. Chapman and Hall. Price, 7s. 6d. net.

A companion volume to the one discussed above, comprising a course of practical laboratory work, which may be used in connection with a course in quantitative analysis. The apparatus required throughout is simple and the work is well within the scope of an ordinary University year. Fundamental experiments of a physico-chemical nature, which are usually left to the third year in an English University course, are here presented in a simple and intelligible manner. The experimental work in connection with the theory of indicators is particularly good, and the student who has worked through the course should be well able to comprehend the limitations of the single indicators and the reason for the existence of the great number of compounds now in use.

Perfumes and Cosmetics. W. A. Poucher, Ph.C. London: Chapman and Hall, Ltd.; 21s. net.

An English book, with special reference to synthetics, which certainly deals very thoroughly with practical aspects. There are three main sections—varieties, sources, properties and in many cases formulæ—details of preparation—modern and older cosmetics. It is embellished with many very excellent illustrations, and should prove of considerable value to all of whom the practical side of this branch of chemistry is important.

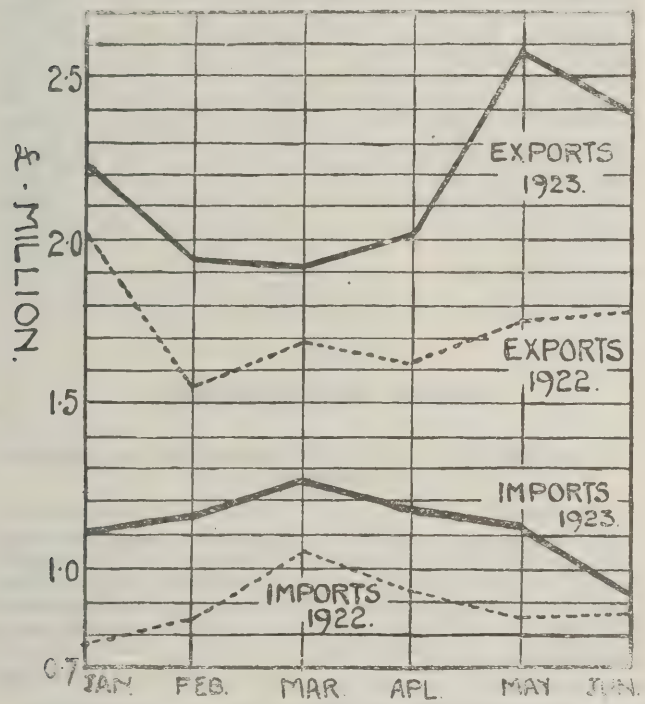
Gesammelte Abhandlungen. (Collected Essays) Vol. II. By Dr. F. Kehrmann. Leipsig, Verlag von Georg Thieme. Paper backs, 600 pages; price, 16s

The author, who is professor of chemistry at the University of Lausanne, presents the results of the researches carried out by himself with the collaboration of his staff and his advanced students. The volume is divided into two parts, the first of which deals with investigations on the hydroquinones and quinones, and the second with the azines and azonium compounds. Many new results are incorporated in the work, such as the discovery of the amino derivatives of benzoquinone, the relationship between the constitution of the hydroquinones and their tendency to quinone formation. Since a quinonoid structure is assigned to all the organic colouring matter by many of our leading tinctorial chemists increased detailed knowledge of the chemistry of this class of compounds should be valuable. The section dealing with the azines and the azonium compounds is the larger, and deals mainly with the azine dyestuffs, such as the safranines and indulines. The complexity of the chemistry of this class of compound is remarkable, and we cannot do more than indicate the general character of this work, which must appeal chiefly to the specialist in limited regions of organic chemistry.

BRITISH OVERSEAS CHEMICAL TRADE.

JUNE IMPORTS AND EXPORTS.

BASED on the statistics published in the Board of Trade returns for June, the foreign trade in chemicals and allied products continues to be satisfactory. It is true that actually the exports of products under the group heading of "Chemicals, drugs, dyes, and colours" have declined from £2,573,000. in May to £2,385,000. in June, but the latter figure still is higher, with the exception of the previous month, than that for any month since February, 1921. Exports during the half year, as indicated in the following graph, have been consistently higher than for the same period in 1922, while imports show an encouraging tendency to fall, the June figure of £933,234. comparing favourably with £1,119,000. in May. During the past six months, total imports of chemicals, drugs, etc., amounted to £6,863,000., an increase of £1,509,000. on the total of £5,354,000. in the same period of 1922. In the export branch an increase over the half year of £2,705,000. is to be recorded, the figures being £13,121,000. and £10,416,000 respectively. This revival is all the more encouraging when it is remembered that values in many export lines have decreased, indicating an even larger increase in tonnage during the past two



Overseas Chemical Trade for the Half-years ending June 30, 1923 and 1922.

months. The weakening of competition from Germany, on account of the dislocation in the chemical industry due to the French occupation of the Ruhr is undoubtedly a large factor in the stimulation of the foreign trade in chemicals of the United Kingdom. So long as the present situation in the Ruhr continues, so long will the British manufacturer have an opportunity of exploiting markets previously supplied from German sources. One of the conditions of settlement in the question of reparations will undoubtedly be the stabilisation, for international purposes, of the mark, at whatever value, and when this takes place one of the greatest—if not *the* greatest—obstacles to the development of the British chemical industry will be removed. The present dullness in the home market, resulting from the uncertain conditions and fear of the future, would also be relieved by the clearing of the political situation.

In the following table are given the imports and exports, by weight, of various representative chemical products, for the months of June and May. The recent dislocation resulting from the exclusion of the Irish Free State from the official returns does not affect this table, as the new arrangement came into force on April 1 last.

IMPORTS—Increases on May Quantities.

		1923. June.	May.

Plumbago Trade of Ceylon.—Statistics published in the report of the Ceylon Chamber of Commerce for the year ended December 31 last show a very satisfactory increase in the exports of plumbago from Ceylon during 1922, the total shipment being 211,235cwt., as compared with 85,153cwt. in 1921. There appear to be signs of a general improvement setting in slowly not only for dusts, but for the higher grades of plumbago as well.

PARLIAMENTARY NEWS.

Surplus Government Property.

In the House of Commons on Wednesday (July 11), Sir W. Joynson-Hicks, replying to Mr. Burgess, said: There are in all some 30 properties under the description of munition factories and some 16 miscellaneous properties, apart from vacant sites, all of which properties are available for disposal. In addition there are 11 factory properties and eight miscellaneous properties at present being used for Government purposes, some of which may hereafter become available for disposal.

Sewage Purification.

Mr. Rhys Davies on Friday (July 13) asked the Minister of Health: Whether his attention has been called to the process of sewage purification covered by the world's patents which are the property of the Septic Gas Company of Australia, Limited; whether he is aware that it is claimed that a mechanical self-contained process has been discovered for the purification of sewage and trades waste by the production of gas, without the formation of organic sludge, whereby the pollution of air, land, and river is eliminated, and that the gas produced as a result is the purest and of the highest calorific value and is highly suitable for the working of any type of internal-combustion engine; and whether, having regard to the vast sums expended on the disposal of sewage, he will institute an inquiry into the merits of this process?

Mr. Chamberlain: I am aware of the process to which the hon. member refers, and my Department is watching this and various other experiments which are being made for producing gas from sewage. I am advised, however, that the particular process referred to by the hon. member is essentially a process for making gas from sewage sludge, and that it should not be assumed that its adoption would obviate the need for other measures of purification.

White Lead in Painting.

On Thursday (July 12), a debate took place on the Home Office estimates, in the course of which Mr. Locker-Lampson, speaking on behalf of the Home Secretary, in regard to the White Lead Convention of 1922, said: A good many hon. members think that the Convention of 1922 at Geneva ought to be recognised. As a matter of fact, the present Minister of Labour was present at Geneva, and he agreed to the terms of the agreement, but unfortunately since that date a certain misunderstanding has arisen about one of the principal agreements under the Convention—the employment of young people under 18 and the employment of women for industrial purposes. Apparently a good many of the members at Geneva were under the impression that that Article referred only to the painting of houses. Other members declared they believed it referred to the whole of industrial painting, whether in regard to houses or not. Until that point has been cleared up satisfactorily, it is rather difficult for this country to agree to the ratification of the Convention.

SOUTH WALES NOTES.

[Specially Contributed.]

Some uneasiness is being experienced in the tinplate industry. Several demands put forward by the men have been rejected by the employers, the four claims accepted being of a modified character. The Industrial Council are to be called together on the 30th inst. to discuss the affairs. The patent fuel trade still keeps active, and makers have sufficient orders to keep their works going for several weeks. There is a good supply of small coal. The nickel trade is improving there being a better demand for the metal, while residuals are in good call. Cokes are much more active and the ovens are now in full operation. By-products are selling well, though sulphate of ammonia is being put to stock, that material being a neglected market at present. The copper situation does not improve and there are several works idle. Sulphuric acid is steady, and the output is showing a gradual increase. Among the imports for the week to Cardiff were 10 tons rock salt, 64cwt. zinc oxide, 12 casks lithopone from Hamburg; to Swansea, 108cwt. red oxide, 15 tons magnesite from Hamburg, 30 tons zinc ashes, 6 tons lead ashes from Libau, 1,860cwt. nickel oxide from Montreal; to Newport, 2,000 tons iron pyrites from Huelva. Included in the exports were 54 tons sulphate of iron to Hamburg from Newport.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

The depression in the hematite pig-iron trade though more extensive this week than last has not yet affected West Cumberland, and for that reason the coal and coke industries continue to be very briskly employed. If the uncertainty as to the result of the efforts being made to clear up affairs in the Ruhr is prolonged, a curtailment of iron production here as well as in the Furness districts seems inevitable. However, the position this week is that all the coal that can be raised is being disposed of, and that the make of coke is likewise being absorbed. Practically all the smalls are going to the ovens. Of the coking industry it should be noted that there is now a spirited Continental demand. It has apparently arisen during the last few days, though it may be remembered that some time ago it was stated in this report that there would be substantial shipments for export in August. What is taking place is that coke is being sent to the Continent at the rate of between 1,000 tons and 2,000 tons per week. The price is a little in excess of that being paid locally. Hematite pig-iron smelters under the new iron ascertainment are paying from 35s. to 37s., and the Continent from 35s. to 40s. per ton. Residuals are all a good market. The tar is going to the chemical works, and sulphate of ammonia is moving away satisfactorily. Crude benzol is in good request at higher rates and creosote and road tar are being marketed quickly. There is a further drop in the imports of East Coast coke, the total this week being short of 6,000 tons, that being due of course to damping down of furnaces in the Furness district.

LEGAL INTELLIGENCE.

DISPUTE OVER TAR AND AMMONIACAL LIQUOR CONTRACT.

Brotherton and Co., Ltd. *v.* Glasgow Corporation.

At the Edinburgh Court of Session on Thursday (July 12), an appeal by the plaintiffs was heard against Lord Blackburn's judgment in the action by Brotherton and Co., Ltd., ammonia and tar distillers, Leeds, against the Corporation of Glasgow. In October, 1904, the plaintiffs entered into a contract with the defendants whereby they acquired from them right to certain chemical works, buildings, and ground appertaining to the gas works at Provan, and also to the tar and ammoniacal liquor produced by the defendants in the course of their manufacture of gas. The duration of the contract was for five years from July 1, 1904, but on its expiry a new contract for a period of five years was entered into. A third contract extended it for an indefinite period. The contract was finally terminated on July 31, 1920, by the defendants, and they took over the works on that date, and had since carried them on themselves. The parties were at issue as to the construction of an article of the contract which dealt with the price to be paid by the plaintiffs for the tar and ammoniacal liquor supplied to them by the defendants under the contract. In the Outer House, Lord Blackburn gave judgment for the defendants, holding that the plaintiffs construction of the article was erroneous. The Court recalled the interlocutor of the Lord Ordinary and allowed parties a proof.

The Lord President said he was not prepared to accept the construction which the Lord Ordinary had given to the Article. There was more than one possible construction open to the article, and in all probability the choice of which ought to be selected as the true one might be very greatly affected by the way parties had conducted themselves in relation to the contracts up to 1916. There was apparently no prospect of agreement as to the facts, and his Lordship saw no alternative but to send the case back to the Lord Ordinary in order that parties might have an opportunity of clearing up these matters.

FERTILISER NEWS.

Nitrate of Soda.—There seems to be little doubt that the United States, as the largest individual purchaser of Chilean nitrate, is becoming increasingly dissatisfied with the system of price-fixing adopted by the producers of the material. The lack of interest in the American spot market for some little time testifies to the belief that prices may weaken, instead of rise, later on. As has been stated in this column previously, the Government had ordered a comprehensive investigation into the nitrate industry, certain representatives of the United States visiting Chile to obtain first-hand information as to processes and costs of manufacture, while the conditions in the European market were being closely studied at the same time. The Government have now taken further steps, and the Department of Agriculture has issued to the Press a report, apparently based on information supplied by the investigator visiting Europe, in which it is stated that the present system of fixing the price of nitrate is inimical to the interests of consumers. It is complained that the United States, despite the fact of its premier position as a consumer, has no say in the matter of prices. In fact, in the actual words of the report "the evolution of the nitrate trade is operating to give Great Britain a strong advantage over the United States." The report further states "in theory, the price-fixing is done by a committee in Chile, but in reality by a London sub-committee, whose recommendations are almost invariably adopted." In the light of this very definite statement, the views expressed by the various chairmen at the recent shareholders' meetings of the English nitrate companies regarding the new season's prices, can be understood. At most of these meetings, it was regretted that the scale of prices had not been fixed at a higher level, but these regrets now appear to be something in the nature of propaganda. By making public announcements of this nature, the agriculturist, already heavily burdened, is led to believe that things might have been worse!

Sulphate of Ammonia.—The export tonnage of British sulphate again increased in the month of June, reaching the satisfactory total of 24,065 tons, compared with 21,476 tons in May and 11,563 tons in June of last year. Customers during the month, in order of importance, were Spain and the Canaries 7,955 tons, Japan 4,790 tons, the Dutch East Indies 3,838 tons, British West Indies 1,114 tons, France 433 tons, and Italy 360 tons, while countries not specially mentioned accounted in the aggregate for 5,575 tons. The end of June marks the end of the season, and therefore of the fertiliser year, and it is interesting to note that for the past six months, exports are almost double the quantity recorded for the same period in last year. So far this year, some 123,560 tons of sulphate have been despatched from British ports. This figure becomes more significant when it is remembered that total exports for 1922 were 145,292 tons, for 1921 128,493 tons and for 1920 109,620 tons. There is still much lost ground to regain if pre-war figures are to be reached, exports in 1913 amounting to 323,054 tons. The difficulties of competition, in spite of the factor of increasing consumption, are evident when it is found that America is able, even under the handicap of a great coal and railway strike, to export 147,331 tons last year, against an importation in 1914 amounting to 83,377 tons. There is some talk at the present time in the United States, of the existence of an agreement between the British Sulphate of Ammonia Federation and the leading distributors of American material, touching the apportioning of the world's markets for the commodity. Should such be the case, consumers will hardly welcome such an alliance, governing practically the whole of the available exportable sulphate, Germany being too busy looking after her own requirements under the stress of decreasing production. This rumour, however, is hardly supported by the fact that Japan is taking more sulphate than ever before from Great Britain, total imports for the past six months amounting to 20,392 tons—one sixth of the total exportation. This is all the more gratifying in view of the fact that in the corresponding period of 1922, only 50 tons of British material found its way to Japan. According to the Alkali Inspectors' Report, recently published, the total production in Great Britain of ammonia expressed in terms of 25¾ per cent. sulphate amounted to 351,142 tons, and was made up as follows: from gasworks, 163,863 tons, iron works 3,079 tons, shale works 45,860 tons, coke ovens, producer gas and carbonising works 138,340 tons.

Other Fertilisers.—The total turnover of basic slag during the half year ended June 30 last amounted to practically 17,800 tons, made up of 12,033 tons exported and 5,752 tons imported, against 13,343 tons (exports 5,763 and imports 7,580) in 1922 and 3,206 tons (exports 1,434 and imports 1,772) in 1921. The activity in the iron and steel industries, dating back for some time, is primarily responsible for the improvement, and it is gratifying to see that the relation of exports to imports is now more than 2 to 1. In the home market for this material, there is very little activity, and movements are at a minimum. Exports of compound fertilisers show an expanding tendency, the figure for 1923, up to the end of June, amounting to 29,619 tons, compared with 15,780 tons in 1922 and 6,456 in 1921. On the raw materials side, imports of raw guano during the first six months of this year, at 10,954 tons, are just double the quantity brought in in the same period of last year, and compare still more favourably with 4,050 tons in 1921. This increasing importation is reflected in the larger trade in the compound fertilisers noted above. Shipments of phosphate rock have been on a declining scale, imports for the half-year being 171,802 tons against 191,663 tons in 1922 and 212,685 tons in 1921. This may be accounted for by the fact of the depression existing for so long in the superphosphate industry of this country. Large imports of foreign superphosphates at prices below the cost of manufacture in this country have contributed in no small degree to the decline, while high prices for raw materials, and the general poverty of the agricultural consumer have added to the troubles of the superphosphate producer.

TRADE +GF+ MARK.

Malleable Tube Fittings

GAS, STEAM, and WATER, ⅛in. to 6in.

Invaluable to Chemical Manufacturers and Merchants, Tar Distillers, Paint and Varnish Makers, Oil Producers and Users.

IN USE BY HUNDREDS OF FIRMS ALL OVER THE WORLD.

Send postcard for complete contents.

Obtainable, price **7/6** post free, cash with order, from BANDON & MORRIS, 17, Red Lion Passage, High Holborn, London, W.C. 1.

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS IN JUNE.

THE following returns, which are taken from the import statistics of the United Kingdom, give the amount and value of chemicals and allied products imported during the month of June, 1923, compared with 1921 and 1922. As from April 1, 1923, the import trade of the Irish Free State is excluded from the returns.

(To be concluded.)

REPORTS OF COMPANIES.

Welsbach Light Company, Ltd.

The ordinary general meeting was held in London on Thursday (July 12), Mr. J. R. Yates (the chairman) presiding. The Chairman in moving the adoption of the report and accounts and the declaration of the dividend and bonus recommended, said that despite foreign and other competition, they sold more mantles last year than in the previous year, and considerably more sundries. In both cases they sold at lower prices, and, while in the case of mantles their aggregate receipts in pounds sterling were below those of the previous year, in the case of sundries, notwithstanding the lower prices, they were in excess of those of the preceding year. The company's advertising campaign had been one of the most extensive character of any in its history. The range of their burners had been considerably increased, partly in the development of aluminium burners, but especially in superheater and economy burners. They had broken fresh ground by introducing highly efficient electrical appliances for various uses on the table and elsewhere, the sales of which showed progress.

The motion was adopted.

Forth Glass Works, Ltd.

Accounts show that, after deduction of £597. for depreciation, there is a loss for the year to March 31 last of £2,623.; to this there falls to be added the debit balance from the previous year of £4,819., leaving a balance at debit of profit and loss account of £7,442. Report states that during the past year the trading conditions continued to be unsatisfactory and the works were on short time throughout the year.

Cape Asbestos Company, Ltd.

After providing for taxation, doubtful debts, and including income from Capamianto S.A.I., Turin, the profit for 1922 amounted to £13,840. (against £17,396. for 1921). Adding £9,422. brought forward, the total available is £23,263. An addition of £5,000. (the same) is made to reserve, and a dividend of 10 per cent., less tax, is proposed on the ordinary shares (the same). This dividend requires £5,273., and the preference shareholders receive an equivalent amount (under the terms of issue), in addition to the fixed 5 per cent. dividend. A balance of £5,504. is carried forward.

DIVIDENDS.

John Knight, Ltd.—Dividend on the 25 per cent. cumulative preferred ordinary shares, at rate of 12½ per cent. for half-year to May 31, 1923.

Major and Company, Ltd.—Net profits for 1922 were £30,403., and £2,140. was brought forward. A dividend on the ordinary shares of 10 per cent. is proposed, carrying forward £2,443.

South Metropolitan Gas Co.—Interim dividend declared at rate of 5 per cent. per annum, less tax, on ordinary for half-year.

Courtalds, Ltd.—Interim dividend of 1s. 3d. per share, free of income-tax. The total dividend for 1922 was 15 per cent., which included an interim distribution of 6¼ per cent. (1s. 3d.), paid in August last year.

Boots Pure Drug Company, Ltd. — The directors have declared an interim dividend of 9 per cent. (less tax) on the new ordinary shares with respect to the quarter ended June 30, 1923.

Gas Light and Coke Company.—Dividends for the half-year ended June 30, on the 4 per cent. consolidated preference stock at the rate of £4. per cent. per annum, on the 3½ per cent. maximum stock at the rate of £3. 10s. per cent. per annum, and on the ordinary stock at the rate of £5. 4s. per cent. per annum. Similar dividends were declared a year ago.

Electrolytic Zinc Co. of Australasia, Ltd.—Dividend at 8 per cent. per annum on the ordinary shares for the six months ended June 30 (against nil), and at the same rate on the 8 per cent. participating preference shares.

Mather and Platt, Ltd.—Interim dividend of 5 per cent., actual, on the ordinary shares, tax free.

International Nickel Co.—Directors have declared quarterly dividend of 1¼ per cent. on preferred stock.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, whence, unless otherwise stated, further information may be obtained.

Belgium.

A Belgian agent in Brussels desires to secure the representation, on a commission basis or otherwise, of British manufacturers of shellac, Manilla gum, fish glues, and chemical products. (Ref. No. 31.)

A Belgian firm at Liége desire to secure the agency of British manufacturers or exporters of beeswax, turpentine essence, stearine, talc, carnauba wax, petroleum jelly, coconut, cotton-seed and soya-bean oils, calcium carbonate, calcined magnesite, and gum tragacanth. (Ref. No. 35.)

Czecho-Slovakia.

An old-established retail chemist in Bratislava is desirous of obtaining the sole agency for Slovakia, or for the whole of the republic, of a British firm of wholesale chemists. (Ref. No. 37.)

Denmark.

A firm of agents in Christiania are desirous of securing the agency in Denmark of a British merchant supplying agar agar. (Ref. No. 38.)

Netherlands.

An old-established and experienced agent at The Hague desires to obtain the sole representation for the Netherlands of British manufacturers of toilet articles, lavender water, and soap. (Ref. No. 45.)

United States.

A San Francisco firm of import and export merchants are desirous of receiving c.i.f. quotations for linseed and refined deodorised rapeseed oil. In the case of the former the company wish to deal with London exporters alone, and in the case of the latter only with manufacturers. (Ref. 20,066/F.W./C.C.2.)

NEW COMPANIES.

Associated Paint Manufacturers, Ltd.—Capital £5,000. Min. sub. £7. Solicitors: J. D. Langton and Passmore, 57½, Old Broad Street, E.C.

Tarslag (1923), Ltd.—Capital £250,000., in 150,000 8 per cent. cum preference shares of £1. and 1,000,000 shares of 2s. Solicitors: Coburn and Co., 6, Drapers Gardens, E.C.

British International Industries Ltd.—Private company. Capital £1,000. To acquire, develop, and turn to account chemical, manufacturing, and other formulæ. Office: 3 and 4, Clement's Inn, W.C.

Cleveland Scientific and Technical Institution.—Limited by guarantee. Secretary: Lt.-Col. E. L. Johnson, Corporation Road, Middlesbrough.

F. Lamplough and Co., Ltd.—Private company. Capital £4,000. 1s. shares. Oil and manufacturing chemists. Office: 25, Victoria Street, S.W. 1.

Lafarge Aluminous Cement Co., Ltd.—Private company. Capital £30,000. £1. shares (17,000 preferred ordinary and 13,000 deferred). Solicitors: Linklaters and Paines, 2, Bond Court, Walbrook, E.C.

Pierre Roustan (Grasse), Ltd.—Private company. Capital £1,000. Manufacturers and sellers of perfumes, lotions, etc. Office: 36. Mincing Lane, E.C.

New American Alcohol Denaturant.—The American Commission of Internal Revenue has authorised a new denaturant for alcohol used in the manufacture of fungicides, insecticides, deodourants and similar substances. The formula provides that for every 100 gals. of ethyl alcohol, there shall be added half a gallon of benzol and one gallon of the following solution: 5 gallons of an aqueous solution containing 40 per cent. nicotine, 0.4lb. of the acid yellow dyestuff Fast Yellow Y, 0.4lb. of Tetrazo Brilliant Blue 12B conc. and water to make 100 gallons.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

July 2 to 7 (inclusive).

Rotary Pumps for Gases. Akt.-Ges. Brown, Boveri, et Cie. 17,372.
Extraction of Liquids from Paper Pulp, Sewage Sludges, etc. Ardern, E.; and Huebner, J. 17,537.
Metal Catalyst. Barker, R. W. (*Vegetable Oil Securities Co.*). 17,221.
Recovering Ammonia from Gases or Vapours. Bone, W. A.; and Finch, G. I. 17,681.
Lime-sand Concrete. Caccia, R. 17,238.
White Lead. Campbell, F. H.; Clapp, F. B.; and Lloyd, G. F. 17,278.
Aminobenzoyl Derivatives of 1-methyl-4-diethylaminopentanol-5 and 2-methyl-4-dimethylaminopentanol-5. Chemische Fabrik Flora. 17,375.
Breaking Emulsions. Dixon, W. H.; and Hood, A. V. 17,386.
Artificial Marble. Douzal, E. 17,484.
Carboxylic-acid Chlorides. Farbwerke vorm. Meister, Lucius, and Brüning. 17,390.
Sizing Liquor. Grundy, R. E. 17,053.
Combined Developing and Fixing Compositions. Hashimoto, H. 17,138.
Drying Clay, Bone, Paint, etc. Hobson, W. 17,172.
Water Gas. Humphreys and Glasgow, Ltd. (*Evans*). 17,269.
Alkaline-earth Metal Compounds of the Organic Phosphorus Compound in Milk Casein. Imray, O. Y. (*Soc. of Chemical Industry in Basle*). 17,388.
Catalytic Reactions. Johnson, J. Y. (*Badische Anilin and Soda-Fabrik*. 17,467.
Aqueous Solutions for Producing Gases for Power or Fuel. Kelly, T. D. 17,576.
Cellulose Solutions. Lilienfeld, L. 17,130.
Cleaning Gases. Lodge-Cottrell, Ltd. (*Metallbank-und Metallurgische Ges.*). 17,147.
Electrical Precipitation of Suspended Particles from Gaseous Fluids. Lodge-Cottrell, Ltd. (*Metallbank-und Metallurgische Ges.*). 17,329.
Varnish. Mohlman, G. F.; and Snape, J. W. 17,265.
Obtaining Organic Super-oxides in a Finely Divided Condition. Naamlooze Vennootschap Vereenigde Fabriken van Chemische Producten. 17,256.
Separating Impurities in Suspension from Liquids. Petree, C. G. 17,480.
Iron Oxide for Purification of Coal Gas. Plausen's (Parent Co.), Ltd.; and Schotz, S. P. 17,290.
Calcining Kiln. Reber, J. W. 17,456.
Cement. Rigby, T. 17,285.
Diethylchloracetamide. Soc. Chimiques des Usines du Rhône. 17,466.
Aqueous Solutions from Difficultly Soluble Gums. Soc. Italiana E. De-Angeli per l'Industria dei Tessuti Stampati. 17,663.
Sulphurised Dyestuffs. Soc. of Chemical Industry in Basle. 17,389.
Burning of Sulphur. Texas Gulf Sulphur Co., Inc. 17,237.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 1s. *in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.*

1921.

Hydrazine. Joyner, R. A.; and Nobel's Explosives Co., Ltd. 34,970. **199,750**
Vegetable Charcoal. Bonnard, L. H. 35,127. **199,751**

1922.

Flotation of Particles of Solid Matter. Eldred, B. E. 383. **199,753**
Dyeing of Cellulose Acetates. Clavel, Dr. R. 415. **199,754**
Evaporators with Tubular Heating-elements. Griscom-Russell Co. 2,522. **186,028**
Aqueous Solutions of Formaldehyde. Hirchberg L. M. 5,212. **199,759**
Formaldehyde by Catalysis. Hirchberg L. M. 5,214. **199,760**
Continuous Production of Low Boiling-point Hydrocarbons from Petroleum Oils. Hanna, R. W. 5,784. **199,766**
Azo Dyestuffs. Bloxam, A. G. (*Chemische Fabrik Griesheim Elektron*). 6,256. **199,771**
Anti-syphilis Substance. Marks, E. C. R. (*Bergel, Dr. S.; Chemische Fabrik Grünau Landshoff and Meyer Akt.-Ges; and Kahlbaum Chemische Fabrik Ges., C. A. F.*). 8,483. **199,784**
Preventing Oxidation. Hancock, L. J.; and Hancock, T. R. 8,591. **199,787**
Purification of Clay. Feldenheimer, W.; and Plowman, W. W. 8,817. **199,795**
Evaporating-pans. Pallister, F. 9,329. **199,829**
Sprinklers for Gas-scrubbers, Cooling-towers, and the Like. Still, C. (firm of); and Kuhn, A. 9,878. **199,847**
Rotary Filters. Plauson's (Parent Co.), Ltd. (*Plauson, Dr. H.*). 10,121. **199,853**
Therapeutically Active Acridine Derivatives. Imray, O. Y. (*Farbwerke vorm. Meister, Lucius, and Brüning*). 11,034. **199,870**
Oxidation Processes. Johnson, J. Y. (*Badische Anilin and Soda Fabrik*). 12,345. **199,886**
Retorts and Method of Protecting the Same. Fairweather, H. G. C. 13,621. **199,900**
Bating and Liming Hides or Skins. Moeller, Dr. W. 16,516 **199,937**
Purification of Hydrofluoric Acid. Howard, H. 25,221. **186,606**
Thermo-resistant Glassware. Nieuwenburg, C. J. van. 29,884. **200,020**
Extracting Sodium Bicarbonate and Other Salts Contained in Natural Soda Bicarbonated Mineral Waters. Appareils et Evaporateurs Kestner. 30,103. **188,335**
Zinc Electrolytes. Bianco, C. 31,376. **192,041**

1923.

Disinfectant Washing-powder. Grimshaw, A. 1,258. **200,033**
Porous Material for Use with Compressed Acetylene. Acétyléne Dissous et Applications de L'Acétyléne. 15,338. **199,394**

COMPLETE SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

1923.

Mixed Fertiliser by the Utilisation of Distillers' Wash or Similar Organic Matters. Soc. E. Coppée et Cie. 14,304. **200,070**
Metal-iodide-alkali-iodide Compounds. Truttwin, H. 15,876. **200,081**
Polymerisation Products of Acetylene. Elektrizitätswerk Lonza. 16,283. **200,087**

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Thymol. Howards and Sons, Ltd., Ilford; and J. Blagden, South Woodford, both in Essex. British Patent, **197,848**, of 1922.

Thymol is prepared by sulphonating *m*-cresol under conditions suitable for producing a polysulphonic acid, such as the di- or even tri-sulphonic acid, which is then condensed with isopropyl alcohol, the sulphonic groups split off and the thymol steam-distilled. According to an example *m*-cresol is treated with oleum, containing 88 per cent. total sulphur trioxide, first at 100° and then at 150° C. A solution of isopropyl alcohol in sulphuric acid is run in and the mixture maintained at 80-90° C. for several hours. It is then heated to 130° C. and a current of steam passed in, the thymol distilling off. A small quantity of by-product may be removed by solution of the thymol in alkali. A little isomeric thymol, melting at 114° C., is also formed.

Dyestuffs for Cellulose-acetate Silk. A. G. Green and K. H. Saunders, Manchester; and British Dyestuffs Corporation, Ltd., London. British Patent, **197,809**, of 1922.

N-Methyl-ω-sulphonic acids of diamido-azo compounds are obtained by sodium sulphide reduction of compounds of the general formula $X\text{-}N_2\text{-}Y\text{-}NH.CH_2.SO_3H$ or $X\text{-}N_2\text{-}Y\text{-}N_2\text{-}Z\text{-}NH.CH_2.SO_3H$ (in which X contains a *p*-nitro group), the N-methyl-ω-sulphonic groups remaining intact; a second ω-sulphonic residue can then be introduced into the molecule by treatment with formaldehyde bisulphite. Examples are gives of the reduction with cold sodium sulphide solution of monoazo dyes from diazotised *p*-nitraniline and the sodium N-methyl-ω-sulphonates of aniline, 2-amido-4-cresolmethyl-ether, and α-naphthylamine, and of the secondary disazo dye from *p*-nitraniline, 2-amino-4-cresolmethylether, and aniline-N-methyl-ω-sulphonate of sodium; the last named dyestuff may be diazotised upon the fibre and developed. The compounds which contain no sulphonic group in the nucleus are of especial value in dyeing acetyl silk. Specification 11343/99 is referred to.

Phosphorus Pentoxide. Sir R. Threlfall, Birmingham. British Patent, **197,863**, of 1922.

Phosphorus pentoxide made by burning phosphorus in a stream of dry air is condensed at a temperature of 125 to 200° C. in a compact, crystalline form. To avoid the presence of a small amount of the amorphous, bulky variety a portion of the vapour at about 160° C. is led through a filter containing glass wool to a second condensing chamber.

Catalytic Apparatus. I. W. Cederberg, Berlin, and H. M. Bäckström, Djursholm, Sweden. British Patent, **197,872**, of 1922.

Apparatus for carrying out exothermic catalytic reactions in gases, particularly the oxidation of ammonia and the production of sulphuric anhydride, comprises a series of rings in which the contact elements are supported, and which when pressed together, as by bolts, form a gas-tight chamber having inwardly and outwardly projecting flanges. The flanges serve to dissipate the heat of the reaction, and at the same time ensure that no portion of the gas flow shall evade passage over or through the contact material. The contacting faces of the rings are preferably conical; and in the case of an ammonia-oxidation apparatus, the rings are preferably of aluminium or a nickel alloy.

Recording Filter-bed Resistance. W. G. Kent, London. British Patent, **197,736,** of 1922.

Records of the resistance of a filter bed and of the rate of flow therethrough are made on drums, rotated by clockwork and preferably coaxial, by pencils whose movements are controlled by the movements of rocking beams or wheels, each connected to two displacers. The chambers for the displacers of the resistance record are respectively connected to a pipe leading from just above the filter bed and to a pipe leading from just below the bed. The chambers for the flow record are connected respectively to a constriction or throat on a pipe through which the filtered liquid flows and to the upstream end of the pipe.

Alkali Thiosulphates and Barium Salts. Rhenania Verein Chemischer Fabriken Akt.-Ges. Zweigniederlassung Mannheim and F. Rusberg, both in Mannheim, Germany. British Patent, **197,898,** of 1923.

Alkali thiosulphates are obtained by passing sulphuretted hydrogen into a solution of alkali bisulphite and sulphite. The sulphuretted hydrogen is advantageously obtained by lixiviating crude barium sulphide, and treating the solution with an acid such as carbonic or hydrochloric acid or similarly acting substance; or by treating crude barium sulphide mixed with water with an acid such as dilute hydrochloric or nitric acid or a similarly acting substance such as magnesium chloride, the corresponding barium salts being obtained in either case.

Ammonium Sulphate. Pease and Partners, Ltd., and G. Stephenson, Darlington. British Patent, **197,724,** of 1922.

Gases containing ammonia, such as coke-oven gases, are used to neutralise crude ammonium sulphate by arranging the neutralising vessel either in the main conveying the gas from the producer, or in a bye-pass to the main, the residual gases from the neutralisation being then led on to the saturators, scrubbers, or other bye-product recovery plant. Steam may be introduced into the neutralising vessel.

Sulphur Burners. A. T. Prentice, Somerset West, South Africa. British Patent, **197,845,** of 1922.

In a sulphur-burning furnace the primary combustion chamber is surrounded by a flue in which the combustion of the sulphurous gases is completed, and this in turn is surrounded by flues, for heating the primary and secondary air supplies. The primary combustion chamber is fitted with superposed hearths, and the air supply is delivered thereto through the ports. The sulphurous gases and the secondary air pass into the flue through the ports respectively. Valves are provided for regulating the primary and secondary supplies of air.

Pure Chromium. G. Brewer, London. (F. Krupp Akt.-Ges., Essen, Germany.) British Patent, **197,887,** of 1922.

An electrolyte for the continuous separation of pure chromium in thick layers contains chromic acid, a salt of trivalent chromium and chromium chromate, the amount of chromic acid being at least more than double that of the chromic oxide. The ratio of the current density at the anode to that at the cathode must be such that all the lower oxides produced at the cathode are oxidised continuously at the anode to chromium trioxide. In an example, the bath contains 25 per cent. of chromium trioxide, a little chromic sulphate, a little sulphuric acid and a little chromic oxide; it is electrolysed without a diaphragm at ordinary temperatures with lead peroxide anodes with a current density at the cathode of 10 amps per sq. dem. and at the anode of 5 amps per sq. dem. Chromium trioxide is added as electrolysis proceeds. Specification 1344/68 is referred to.

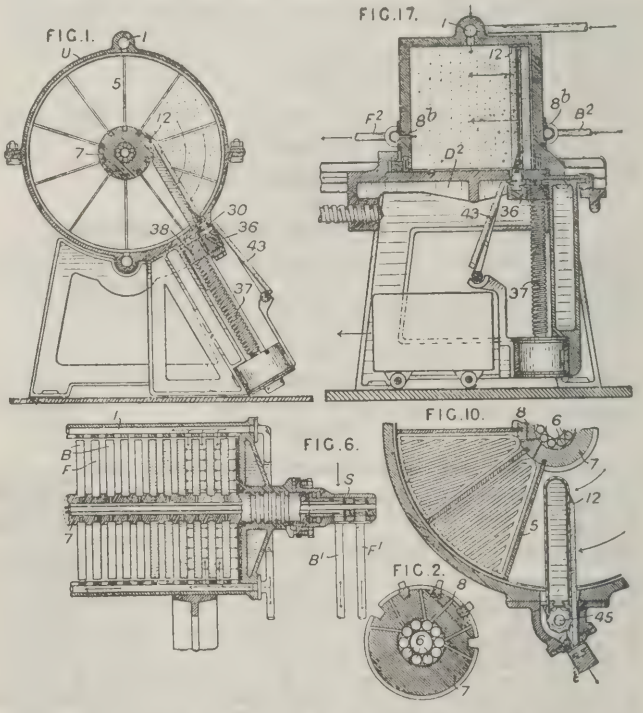
Colloids in Electro-Deposition. A. Classen, Aachen, Germany. British Patent, **197,885,** of 1922.

Colloids having the property of preventing the generation of hydrogen at the cathode are added to a bath for depositing glossy metallic coatings, for example, a coating of zinc on iron. A suitable addition may be prepared by covering a jelly containing gelatine with hydrogen peroxide until it liquefies. Other colloids such as gum, albumen, starch, or dextrin may be used instead of gelatine. Persulphates, perborates, percarbonates, persilicates, perphosphates, pyroperphosphates, persulphuric acid or permonosulphuric acid may be used instead of hydrogen peroxide, and are preferably acted upon—*e.g.*, by sulphuric acid so as to yield hydrogen peroxide.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Rotary and other Filters. H. Jung, Berlin. British Patent, **197,910.** Convention date, May 19.

Rotating-disc filter elements F, B, Fig. 6, are built up of sectors, mounted between spokes 5, Figs. 1 and 10, on a shaft 7 in a casing U to which the material to be filtered is supplied by pipes 1. The shaft 7 is hollow, and contains two series of pipes 6, Fig. 2, with which the elements are in communication alternately through passages 8. A stationary outlet-head S at one end of the shaft has apertures and passages which place one series of the pipes 6 in communication with the pipe F^1 and the outer series with a pipe B^1. When cakes have formed between the elements, treating fluid introduced through the pipe B^1 and elements B passes through the cakes to the elements F, and away by the pipe F^1. The solid matter forming the cakes is subsequently discharged from the casing by means of claws 12 which, with cones or valves 30—which close the necessary openings in the casing—are attached to a longitudinal rail 36 and a nut 38, which is reciprocated by means of a screw-spindle 37. During the operation of the claws, the filtering elements are slowly rotated, so that the cake is removed in strips, and directed away by a resiliently-supported plate 43. Fig. 10 shows an arrangement in which two claws 12 are attached to a chain passing round a driving-wheel 45. The apparatus shown in Fig. 17 has square filter elements which do not rotate,



but are connected by passages 8^b with pipes F^2, B^2 alternately. For the discharge of the cakes the lower wall D^2 of the casing is arranged to slide transversely, carrying with it the claws 12 and the connected parts, and the cakes are removed in strips as with the apparatus described above. Or the casing may move transversely relatively to the wall D^2 and the discharging apparatus. The Specification describes an arrangement in which all the valves used in apparatus of this type, including valves which control the supply of material under treatment, of different fluids to treat the cakes formed and cleanse the filter elements, and of fluid for actuating the cake-discharge devices, are operated pneumatically and automatically in the required sequence, a switch and indicator board being provided with means for regulating the duration of the several cake-treating processes.

GAZETTE NEWS.

SATISFACTIONS.

Industrial Chemical Co. Ltd., London, E.C.—Satisfaction registered July 4, £1,210., registered October 9, 1914.

Western Laboratories Ltd., London, W.—Satisfaction registered June 27, all moneys, etc., registered October 18, 1922.

BANKRUPTCY INFORMATION.

Wheatly, Albt. Edwd., 170, Lord Street, Southport, late trading as Confectioners' Colour and Essence Co., 20, Wood Street, Liverpool. Adj. July 3.

de Cesari, Enea, 9, Ampthill Square, Hampstead Road, N.W., manufacturer of vermin killer. June 6. Discharge suspended for two years.

DISSOLUTIONS OF PARTNERSHIP.

(*Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.*)

Oldfield, Pattinson and Co. (Thos. Ross Pattinson, Hy. Keeler Oldfield, and Wm. Ross Pattinson), Umpire Buildings, New Bridge Street, Manchester, wholesale druggists, April 30. Debts by H. K. Oldfield, who continues. (July 3).

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

British Boiler Fluid and Engineers' Stores Co., Ltd.; chemists; £11. 1s. 11d.; June 4. Registered office: 23, Tanner street, S.E.

Bitumen Products, Ltd.—Resolved June 2, confirmed June 27: That the company be wound up voluntarily. G. F. Todd, 224, St. Vincent Street, Glasgow, liquidator.

THIRTY-FIVE YEARS AGO.

(From the "Chemical Trade Journal," July 21, 1888.)

Society of Chemical Industry.—We were unable from want of space in our last issue to give a full report of the address delivered at the Bute Hall of the Glasgow University, by Professor Dewar, F.R.S., president. He said that there was no problem at the present time which was more likely to modify in every respect chemical changes on a large scale than the question of fuel. More and more people were struck with the fact that this is becoming either a petroleum age or a natural gas age. One had only to visit the petroleum regions of America and to see the application of natural gas on a vast scale, to be convinced that sooner or later the supply of caloric would be the most telling agent as regarded all our manufactures. This more and more forced a small country to economise. The great development of the paraffin industry in this country, the application more and more largely of and the utilisation of waste products, had in recent years certainly struck everyone as being very closely connected with Glasgow manufactures. Of course he referred to the vast utilisation of the salts of ammonia which had now been undertaken by Scotch ironmasters, of whom three were engaged in the matter. Since the Messrs. Baird, of Gartsherrie adopted the process, practically something like one million cubic feet of gas were treated per diem for the absorption of ammonia yielding about seven tons, while an amount of air weighing 3,000 tons was dealt with. When they considered there the small amount of material to be separated, and the ingenuity of the apparatus, it could not be said that industrial chemistry was dormant in Glasgow.

MARKET REPORTS.

LONDON "OPEN MARKET" REPORT. Wednesday.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals.—The slowness and smallness of business continues to be the main feature of the heavy chemical markets. One or two items are a shade easier, but generally the quoted rates are being fairly well maintained. The continued hold-up of business is certainly due to the grave and uncertain position on the Continent. **Acetic Acid,** 80% technical, £47. to £48.; 80% pure, about £50; 98% glacial, £60. in casks, and £75. in glass demi-johns, ex wharf, London. This item keeps very firm, with spot supplies still very limited. **Acetone,** British Government specification, about £120. per ton. There seems to have been plenty of inquiry about, but very little material available; price as quoted is firm. **Arsenic,** Cornish, white powdered, about £72. to £73. per ton. Supplies are still restricted and the high rates are maintained; business is small. **Alum,** lump, £10. 10s. to £11. per ton, in casks; dealers are offering continental material at these figures, with little doing. **Anhydrous Ammonia,** 99.95%, about 1s. 5d. per lb. The season's business is dropping off; prices are about the same

Barium Chloride, 98/100%, £15. to £15. 10s. per ton for spot parcels; offering here at these prices, with little inquiry received. **Bleaching Powder,** 35/37%, £10. to £10. 10s. per ton. Dealers are quoting continental material at about these levels with the demand poor. **Borax,** commercial, granulated, £26. 10s.; crystals, £27.; powdered, £28.; extra fine, £29.; B.P. crystals £31., powdered £32., extra fine £33. per ton, for home trade only, in free 2 cwt. bags, carriage paid to destination. British makers continue to quote at these levels. Importers are offering under similar conditions at: Commercial, granulated, £25. 10s., and powdered £27. per ton. **Borax Glass,** lump £74., powdered £75. per ton. British makers' prices remain at these figures for home trade only, carriage paid, packages free. **Boric Acid,** commercial, crystals, £50.; powdered, £52.; B.P., crystals £56, powdered £60, extra fine £62 per ton, in free bags, carriage paid to destination. British makers continue to quote at these rates for home trade only; dealers are competing at keen rates. **Cream of Tartar,** 99/100%, 92s. to 94s. per cwt., less 2½%. This material keeps very steady in price, and a fair volume of business has been on the market. **Citric Acid,** B.P., crystals, about 1s. 7¾d. to 1s. 8¾d. per lb. Dealers are offering spot material at these cheaper prices; a fair amount of business has been done. **Epsom Salts,** commercial quality, about £5. per ton, in bags. There has been no improvement in demand. **Formaldehyde,** 40%, about £96. per ton, ex wharf, London. This price is nominal; the market is at a standstill and is likely to remain so until the referee's decision on the recent appeal case is issued. **Glauber's Salt,** commercial quality, about £3. 15s. to £4. per ton, in bags. There has been but the smallest inquiry for this product; quotations unchanged. **Lead Acetate,** brown, about £42. 10s.;

white crystals, about £43. per ton. There has been some inquiry on the market but little actual business, owing to the high prices prevailing. **Litharge,** pure flake, British, about £37. Importers are offering at about £36. per ton. **Lithopone,** 30% continental red seal, about £22. to £22. 10s. per ton. Business has been rather quieter and prices just a shade easier; the market keeps steady. **Ammonium Chloride,** grey galvanising, about £30. 10s. per ton. Spot rates are well maintained at this level, and continental supplies are still interrupted. **Nickel Sulphate,** home trade, single and double salts, £38. per ton, delivered; export, single and double salts, £38. per ton, f.o.b. British makers' prices are quoted unchanged. **Oxalic Acid,** about 6d. per lb. This is a dull feature with the price as quoted not very steady. **Bichromate of Potash,** about 6d. per lb. This market has been dull with quoted rates about the same. **Carbonate of Potash,** 90/92%, about £28. to £28. 10s.; 96/98%, about £32. per ton. This market keeps rather dull and prices as quoted are inclined to weaken. **Chlorate** of potash, crystals and granulated, about 3d. per lb. Very little inquiry is coming to dealers. **Caustic Potash,** 88/92% solid, about £32. 10s. to £33. per ton, in drums. These figures are being mentioned for spot parcels; demand poor. **Permanganate of Potash,** commercial quality, about 9¾d. to 10d. per lb. The market has been rather quieter of late; prices seem fairly steady. **Prussiate of Potash,** yellow, about 1s. 3d. per lb.; a further slight decline in quoted values is recorded, with business confined to small quantities only. **Sulphate of Potash,** 90%, £11. 10s. per ton, ex ship. There is no change on the week. **Mercury,** £10. 10s. to £11. per bottle of 75/76lbs. Spot rates are easier this week, and business is reported poor. **Red Lead,** imported, about £36. per ton. Dealers are doing a little business in small lots. **Salammoniac,** dog-tooth crystals, £48. 10s. to £49. 10s.; medium, £43. to £44.; fine white crystals, £26. to £27. per ton. Dealers holding spot stocks are offering at these slightly easier prices this week, but business has been limited. **Saltcake,** ground and unground, home trade, about £4. 10s. to £5.; export, about £5. 10s. per ton, f.o.b. The demand for home trade has been quieter. **Acetate of Soda,** about £25. 10s. per ton. There is a much firmer tone in this market. **Soda Ash,** 58% light alkali, £7. 12s. 6d. per ton, in bags, carriage paid to destination. British makers are quoting at this figure for home trade only; makers' prices for export vary according to destination **Soda Crystals,** £5. 5s. per ton, in bags, carriage paid to destination. British makers selling at this figure for home trade only, and dealers are offering at keen competitive rates. **Caustic Soda,** 70/72%, £18. 10s.; 76/77%, £20. 10s. per ton, in drums, ex wharf, shipping port. Dealers continue to offer at the cheaper prices reported last week. British makers' prices for home trade only show no change at £19. to £21. 10s. per ton, in drums, carriage paid to destination. Prices for export vary as to destination. **Bicarbonate of Soda,** £10. 10s. per ton, in bags, carriage paid to destination. British makers' price given; dealers are quoting at about level rates. **Chlorate of Soda,** crystals and granular, 2¾d. per lb. Dealers are doing little business, and quoted rates are unchanged. **Cyanide of Soda,** 98/100%, export 8½d. to 9d. per lb.; home trade about 10½d. per lb. British makers quote at about these figures. **Nitrate of Soda,** 96%, about £13 7s. 6d. per ton, f.o.r. Liverpool. The market keeps steady at this unaltered figure. **Nitrite of Soda,** 100%, about £26. 10s. per ton. A slight decline in value is recorded here. **Prussiate of Soda,** about 7d. per lb. This market has been very quiet, and cheaper offers than the price quoted have been on the market. **Hyposulphite of Soda,** pea crystals, about £15. 10s per ton, in 1cwt. kegs, on the spot; commercial quality, about £10 10s. per ton, in casks. These prices are being mentioned by dealers, but they would probably be shaded for good sales. **Sodium Sulphide,** 60/62% solid, about £14. per ton; ditto, broken, £15. to £15. 10s. per ton, in drums; 60/65% concentrated, about £15. per ton, in casks. Very little business about at present. **Sulphate of Copper,** £25. to £25. 10s. per ton, f.o.b. continent. Offers at about these figures are being made but there is very little business about and the market seems weak. **Tin Crystals,** about 1s. 4d. per lb. The market is unchanged on the week. **White Lead,** imported, about £43. to £44. per ton. Dealers continue to find a little business at about these levels. **Zinc Oxide,** B.P., about £51. 10s.; white seal, about £43. 10s.; 99.5%, about £37. per ton, f.o.r. makers' works. British makers offering at about these prices, with business dull.

Pharmaceutical Chemicals.—Without exception, all reports to hand this week record the market as being very quiet indeed. The little business that has been done has been almost invariably for small quantities only; prices in a number of products are quoted on a lower level this week. **Acetanilid,** crystals and powder, about 1s. 5d. per lb. Values in this article have declined and the market is still weak and dull. **Acetyl-Salicyclic Acid,** B.P., about 3s. to 3s. 1d. per lb. At these slightly easier levels the market seems fairly steady. **Benzoic Acid,** B.P., about 2s. 3d. per lb. Quoted rates are down on the week, but there is very little doing. **Diethylbarbituric Acid,** B.P. (barbitone), about 21s. per lb. This rate is maintained on a dull market. **Salicyclic Acid,** B.P., about 2s. 2d. per lb. This market has been a quiet one, and prices are a shade easier. **Tannic Acid,** leviss, 3s. 3d. to 3s. 6d. per lb. Slightly easier prices are being quoted for large quantities. **Amidopyrin,** about 14s. per lb. There is seldom any inquiry for this article. Quoted unchanged on the week. **Ammonium Bromide,** 7d. to 9d. per lb., according to quantity. Spot parcels seem plentiful, with not much business about and prices are irregular. **Benzonaphthol,** about 5s. 6d. per lb. Somewhat dearer rates are asked this week. **Benzaldehyde 03,** about 3s. per lb. This market remains very flat; quoted rates unchanged. **Betanaphthol,** resublimed, about 1s. 10d. per lb. Some small inquiry about, but not much business. **Calcium Lactate,** 1s. 11d. to 2s. per lb. Slightly firmer rates are now being quoted, with some limited business passing. **Chloral Hydrate,** duty paid, 4s. to 4s. 3d. per lb. The market keeps very steady at about this level, with business moderate. **Creosote Carbonate,** about 8s 9d. to 9s. per lb. This market is a shade firmer on the week. **Creosote,** B.P., about 2s. 2d. There has been no improvement in demand; quoted at unchanged rates. **Guaiacol Carbonate,** about 8s. 3d. per lb., for small quantities. There has been very little inquiry of late. **Hexamine,** about 3s. 10d. to 4s. per lb. These slightly cheaper prices are being quoted for quantities; business is quiet. **Hydroquinone,** 3s. 6d. to 3s. 9d. per lb. At these levels the market seems very steady and a fair volume of business has been done. **Methyl Salicylate,** 2s. 5d. to 2s. 6d. per lb. The lower rate is being quoted for good quantities; at these prices the market seems steady. **Methyl Sulphonal,** about 15s. per lb. Hardly any movement in this product; quoted unchanged. **Paraformaldehyde,** 3s. 9d. to 4s. per lb. This market is a shade firmer this week. **Paraldehyde,** 1s. 5d. to 1s. 6d. per lb. Values are well maintained at about these levels; business limited. **Phenacetin,** about 6s. 3d. to 6s. 6d. per lb., according to quantity. Spot goods are on offer; business has been quieter. **Phenazone,** about 7s. 3d. to 7s. 6d. per lb. There is a slightly easier tendency in this market and business has fallen off. **Phenolphthalein,** 6s. 6d. to 6s. 9d. per lb. Further material advances have taken place and the market holds very firm. **Piperazine,** about 4s. 6d. per oz., nominal. Some spot offers are said to be much cheaper than this rate. **Potassium Bromide,** B.P., crystals and granular, 6½d. to 7¼d. per lb. There seems to be plenty of material offering on spot, and prices asked are varying very much; the demand is not good. **Potassium Permanganate,** B.P., 10d. to 11d. per lb., as to quantity. At these rates the market seems fairly steady and some fair business has been done. **Potassium Sulphoguaiacolate,** 5s. 9d. to 6s. per lb. Quoted at these prices, with little inquiry on the market. **Salol,** about 2s. 8d. to 2s. 9d. per lb. Slightly easier prices are being asked this week, with business much quieter. **Sodium Benzoate,** about 2s. 6d. per lb. This market remains lifeless. **Sodium Bromide,** B.P., crystals and granular, 7d. to 8d. per lb., as to quantity. The market is not firm at these rates, and some large spot parcels are said to be offering at low figures. **Sodium Diethylbarbiturate,** about 21s. per lb. A sudden advance has been notified here; business seems difficult at this higher level. **Sodium Salicylate,** powder, 2s. 4d. to 2s. 7d. per lb.; crystals, 2s. 8d. to 2s. 10d.; phys. pure flake, 2s. 10d. to 3s. per lb. This market keeps fairly steady, but business has not been at all brisk of late. **Sulphonal,** 14s. to 15s. per lb. lower prices are being quoted here, with the market still dull. **Terpin Hydrate,** about 1s. 9d. per lb. This market keeps very steady, but business is limited. **Thymol,** about 15s. per lb. Spot material offering, but business slow.

Coal-tar Products, Intermediates, Etc.—The only change of importance to record is a firmer tone in pitch. All other items have been decidedly slow of sale, with quoted rates

returned unchanged. **Aniline Oil,** about 9½d. to 10d. per lb., drums free. This market has livened up a little. **Aniline Salt,** about 9½d. to 10d. per lb., casks free. Prices are quoted unchanged on a quiet market. **Betanaphthol,** about 1s. 1d. per lb. Quoted rates are unaltered on the week, with matters slow. **Benzol,** about 1s. 7d. per gallon, f.o.r. makers' works, in buyers' packages. This price is quoted still, but the demand has been very slow of late. **Toluol,** 2s. per gallon, f.o.r. makers' works, in buyers' packages. Business continues to move slowly; quoted prices unaltered. **Xylol,** pure, 2s. 3d.; commercial, 1s. 6d. per gallon, drums extra. Prices show no change on the week; market dull. **Naphtha,** about 1s. 5d. per gallon. This recently lowered rate is so far maintained, but the market is flat. **Solvent Naphtha,** 90/160, 1s. 5d. per gallon, drums extra. There has been but little doing, and quoted rates are unaltered. **Heavy Solvent Naphtha,** 90/190, 1s. 4d. per gallon, drums extra. The market remains dull, with quoted rates unchanged. **Special Oil,** for Diesels and motors, 10d. per gallon, barrels free. This market has shown but little activity of late, and quoted prices remain unchanged. **Burning Oil,** crude, No. 3, 8½d.; No. 2, 8d., per gallon, barrels free. This market continues dull, and prices show no change. **Creosote Oil,** about 10d. per gallon, naked, f.o.b. The market seems quite steady, but business is lacking. **Carbolic Acid,** crystals, about 1s. 2d. per lb. Prices seem to be very irregular, with some offers asking up to 1s. 5d. per lb.; any business about would be at the lower figure. **Naphthalene,** about £20 per ton. The market has been dull and is inclined to be a little easier. Crude, £7. to £13.; crystals, £21.; powder, about £17.; balls, £24.; candles, £28.; tablets, £28. per ton, packages free. **Disinfectants,** 3s. 9d. per gallon, barrels free. Hardly any inquiry about. **Pyridine,** about 18s. per gallon. There does not appear to be any material to offer on spot; quoted price is firm. **Hexamethylene,** 4s. to 4s. 3d. per gallon. The market keeps well up to these rates, and some business has been done. **Pure Methyl Alcohol,** £100. per ton, ex wharf, London. There is no sign of a break in this market; inquiry has been fair. **Pitch,** 135s., London, spot. The market has improved slightly during the week, and the better tone recently reported is well maintained. Forward offers in the region of 147s. 6d. to 150s. per ton are proving of interest.

LONDON METAL MARKET. WEDNESDAY.

Copper: Standard brands, £65. to £65. 2s. 6d., cash; £65. 15s. to £65. 17s. 6d., three months; electrolytic, £72. 10s. to £73. **Tin:** Standard, £171. 7s. 6d. to £178. 10s., cash; £179. 12s. 6d. to £177. 15s., three months; Straits, £181. 7s. 6d.; English, £179. **Lead,** soft foreign, £24. prompt; English, £25. 5s.; chemical sheet, 33s. per cwt. for 2-ton lots, delivered. **Spelter,** prompt, £29. 2s. 6d.; hard, £24. **Antimony,** English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35. **Aluminium,** 98—99%, £115. to £120.; foreign, £110., c.i.f. **Nickel,** £130., delivered; £125. to £130. for export, f.o.b. **Mercury,** £16. 5s **Bismuth,** 10s. **Platinum,** 500s. per oz. **Wolfram,** spot, 13s. per unit, c.i.f. United Kingdom or Continent. **Zinc Dust,** quotations are lower, as follows: Highest grade English, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET. WEDNESDAY.

There has been rather more inquiry for heavy chemicals during the past week, but business as a whole still continues unsatisfactory, and values generally are in buyers' favour. The quotations for alkali products remain steady at recent rates. **Bleaching Powder,** softwoods is quiet at £11. 7s. 6d. on rails. **Chlorates** are dull; **Potash** at 3d., and **Soda** 2¾d. per lb. respectively. **Bichromates** unchanged. **Roasted Saltcake,** firm for home trade, at £4 10s. delivered; demand for export is still brisk. For **Copper Sulphate** there is little or no inquiry, and quotations are nominal at £26. f.o.b. **Phosphate** and **Hypo Soda** are lower; **Nitrite,** firm, at £26. 10s. ex store. Concentrated **Sodium Sulphide,** easy, at £15. per ton. **White Powdered Arsenic** dull, at £70. on rails, Cornish works. **Yellow Prussiate of Potash,** weak, at 1s. 2¾d. per lb.; **Soda,** unchanged, at 6¾d. per lb. **Caustic Potash,** higher, at £29. for 88/90%; **Carbonate,** 90%, steady, at £28. per ton. Grey and brown **Acetate of Lime** are in short supply, and prices have an upward tendency. **Acetic Acid** and **Acetate of Soda** are firmer. **Acetone,** steady, at £120. **Miscible Wood Naphtha,** easier, at 6s. 6d. per gallon. There is not much inquiry for **Lead Salts,** but values are firmly maintained; white **Acetate** at £40., brown £42.; and **Nitrate** £42., delivered. **Copperas** is in good request. **American Rock Sulphur,** steady, at £5 5s. on rails. **Oxalic Acid,** neglected, at 6¼d. per lb. **Permanganate of Potash,** 9¾d. per lb.

SWANSEA MARKET REPORT. WEDNESDAY.

Tinplates moved very slowly and business for forward delivery was practically nil on the basis of £1. 3s. 1½d. per standard box. **Galvanised Sheets,** weak, at £18. 2s. 6d. per ton. **Copper,** fairly active, with firmer prices at £64. 17s. 6d. per ton prompt, and £65. 12s. 6d. three months. **Tin,** very irregular, at £178. 17s. 6d. per ton, cash, and £180. 2s. 6d. three months. **Lead,** more active; soft foreign, prompt £23. 17s. 6d., and forward £23. 7s. 6d. per ton; English £25. 5s. **Spelter,** £28. 12s. 6d. per ton for foreign, prompt, and £28. 17s. 6d. forward. **Zinc Sheets** in fair demand at £38. 7s. 6d. per ton, on rails makers' works. **Sulphate of Ammonia,** quiet, at £14 15s. and £13. 12s. per ton for home purposes; little export, at slightly higher rates. **Sulphate of Copper,** slow, with prompt delivery; £26. 5s. per ton, less 5%. **Nitrate of Soda,** very quiet, at £13. 12s. 6d. per ton. **Bonemeal** slow; Indian, prompt, £8. 17s. 6d. per ton. **Sulphuric Acid,** in steady demand, with easier conditions, at £3. 7s. 6d. to £6. 17s. 6d. per ton, f.o.r. **Oxalic Acid** remains very quiet, at 6¼d. per lb., f.o.r. **Arsenic** is neglected and white powdered on small supplies was quoted £70. 17s. 6d. per ton, f.o.b. **Pitch** met with poor turnover, with lower tendency at £6 12s. 6d. **Copperas,** delivered in bulk, £2 per ton. **Coal** business was of a steady character, with numerous foreign inquiries. Admiralty qualities were firmly held, with best smokeless at £1 10s. to £1. 12s. 6d.; seconds £1. 9s.; ordinaries £1. 8s.; Monmouthshire black vein £1. 8s. 6d. per ton, all f.o.b. **Anthracite** was very firm, with less inquiry. Best large £2 10s., seconds £2 2s. 6d., Paris nuts £3 2s. 6d. per ton, f.o.b. **Patent Fuel,** quiet, from £1 13s. to £1. 15s. per ton, f.o.b. **Cokes,** firmer, especially the foundry grades; export £2. 10s. to £2. 15s. per ton, f.o.b.; foundry £2 to £2 5s., and furnace £1. 10s. to £1. 15s. per ton.

LIVERPOOL CHEMICAL MARKET. WEDNESDAY.

Business in the heavier chemicals continues to be done on a moderate scale, so far as home-trade requirements are concerned. The quietness is generally attributed to the tension between France and Germany and the interruption of trade between these countries and the United Kingdom. Shipments for other foreign countries continue fairly active, so that an element of life is maintained in the market through the movement in the export branch of the trade. **Bleaching Powder** has had a slightly freer inquiry. The price is £10. to £11. per ton for use in the United Kingdom, and £11. per ton for export. **Calcium Chloride** has been in very fair request, the warmer weather having increased the demand for this commodity for brine making. It is £5. 17s. 6d. per ton. **Caustic Soda** has had a steady inquiry for use in the U.K. and a moderate shipment to overseas ports. Quotations are £20. 7s. 6d. to £21. 7s. 6d. per ton for 76%, carriage paid for home-trade use, and £20. 10s. per ton. for export. **Bicarbonate of Soda** has sold with some freedom on home-trade account and has had a moderately active shipment for export. It is £10 10s. per ton, carriage paid, for use in the United Kingdom. **Soda Crystals** have been in fair demand and are £5 5s. per ton for home-trade uses. **Nitrate of Soda** continues quiet and is £13 5s. to £13 10s. per ton. **Borax** has been rather more in request for use in the U.K. and has had a moderate shipment. Commercial crystals are £27. per ton, and powdered £28. Higher grades are: Crystals £31. per ton, powdered £32. per ton, carriage paid in the U.K. **Saltcake** has again been in fair demand for home-trade uses. The price is £4. 10s. to £5. per ton for the U.K., and £5. 10s. to £6. per ton for export. **Bichromates of Soda** has been but little in demand and is 4½d. per lb., c.i.f. to usual ports. **Ammonia Alkali** has been in very fair request for home-trade uses, and has moved rather freely on export

account. It is £7. 12s. 6d. per ton for use in the U.K., and £8. per ton for export. **Hyposulphite of Soda** has been in rather good request. It is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial, and £15. to £16. per ton, in 1cwt. kegs, for photographic. **Sulphide of Soda** has been but little called for. Solid is £16. per ton, and crystals £10. 10s. to £11. 10s. per ton. **Chlorate of Soda** has been in moderate demand, and is 3d. to 3½d. per lb. **Phosphate of Soda** has moved but slowly, and is £15. to £16. per ton. **Prussiate of Soda** has been but little in request, and is 7d. to 8d. per lb. **Yellow Prussiate of Potash** has been rather more in demand, and is 1s. 4d. to 1s. 4½d. per lb. **Red Prussiate** has moved but slowly, and the price is easier; it is 3s. 3d. to 3s. 6d. per lb. **Carbonates of Potash** has had a small sale, and is £26. to £32. per ton, according to quality. **Nitrate of Potash** has had a steady though moderate inquiry, and is £33. to £35. per ton for refined. **Chlorate of Potash** has been very quiet, and is 4d. to 4½d. per lb. **Caustic Potash** has been in slightly freer demand, and is £32. to £33. per ton. **Permanganate of Potash** has been quieter, and is 10d. to 10½d. per lb. **Bichromate of Potash** has had a fair inquiry, and is 5¾d. per lb., c.i.f. to usual ports. **Salammoniac** has moved but slowly. First quality is £63. per ton, second quality £60., and third £57. **Sulphate of Ammonia** has been quiet for home-trade uses, but has had a fairly heavy shipment for foreign ports. Neutral is £14. 15s. per ton, and ordinary £13. 12s. per ton, to the end of August. **Carbonate of Ammonia** has had a steady inquiry, and is 4d. per lb. **Muriate of Ammonia** has been but little in demand, and is £32. to £33. per ton. **Magnesia** continues to meet with a fair inquiry. **Carbonate** is £2. 5s. per cwt. and **Sulphate** £5. to £6. per ton. **Alum** has been in moderate demand. The price is £12. to £13. per ton for home trade and £11. 10s. to £12. per ton for export. **Sulphate of Alumina** has been rather more in demand, and is £8. to £12. per ton, according to quality. **Sulphur** has again been in good request. Flowers are £10. per ton; roll is £8. 10s. per ton; rock £8. to £8. 10s. per ton; and American £5. to £5. 10s. per ton. **Tartaric Acid** has been in fair request, and is 1s. 3d. to 1s. 3½d. per lb. **Cream of Tartar** has been more in demand, and is £4. 14s. to £4. 17s. per cwt. **Boric Acid** has had a slightly freer inquiry. Commercial crystals are £55. per ton, and powdered £58., and £2. per ton more if in casks. **Citric Acid** has been in very fair request, and is 1s. 9d. to 1s. 10d. per lb. **Oxalic Acid** has had a limited inquiry, and is 6¼d. to 6½d. per lb. **White Acetate of Lead** has moved but slowly, and is £42. to £43. per ton. **Sulphate of Copper** has been in moderate demand for use in the U.K., and is £26. to £26. 5s. per ton, less 5%, in casks, f.o.b. at Liverpool. **Arsenic** has been but little called for. White powdered is £71. per ton.

WEST OF SCOTLAND CHEMICALS. Wednesday.

The approach of the holidays is reflected in the easing-off in the demand for chemicals on home account during the week. Export inquiries also continue to be limited. Prices are easier in certain lines, but otherwise nominal quotations still hold steady. The following prices are at Glasgow, unless otherwise stated:—**Alum,** little doing, and in small demand; prices have been reduced and now stand at £12. 5s. for lump, and ground £12. per ton. **Arsenic** continues in short request, and supplies are still very scarce; it is quoted on spot at £77. net. **Barium Chloride** remains very quiet, despite a further reduction to £15. per ton. **Bleaching Powder** does not show much movement, and the quotation still stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax,** granulated, is on offer at £26. 10s. per ton net, in 2 cwt. bags. **Calcium Chloride,** 70—75 per cent. solid, £5. 12s. 6d. per ton. **Citric Acid** is a declining market, though last week's reduced price is maintained at 1s. 8¼d. per lb., less 5%. **Copper Sulphate** is but little in request at last week's figure af £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar,** steady, with better inquiry, and the price continues firm at £4 10s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in quieter demand; brown steady at £40. 10s. per ton, net, and white lower at £40. per ton, net. The market for **Magnesium Chloride** is slow, with quiet business at £3. for spot. **Oxalic Acid,** at 5¼d. per lb., is dull, a substantial decline in price being recorded. **Paraffin Wax** experiences a fair export trade at 2⅞d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull at the rather easier figure of 1s. 4d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1. 11s. per ton, but business is nominal. **Sodium Bichromate** remains steady, with business on the basis of 4½d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2cwt. bags; and £11. 10s. in 1cwt. kegs. **Tartar Emetic,** 43—44%, in fair request at 1s. 1½d. **Tartaric Acid** still shows a quieter tendency at 1s. 3¼d. per lb.

IMPORTS OF CHEMICAL PRODUCTS

At the Principal Ports of the United Kingdom.

GLASGOW.

Week ending July 14.

BARIUM SULPHATE (BLANC FIXE)—
Hamburg, 70 cks.

BARYTES—
Antwerp, 160 bgs.

BITUMEN—
New Orleans, 188 brls.

CARBONATE OF LIME—
Hamburg, 100 bgs.

CASEIN—
Nantes, 22 bgs.

CAUSTIC POTASH—
Hamburg, 31 drms.

CHROME ORE—
Natal, 10 bgs.

CITRIC ACID—
Genoa, 20 brls.

COAL TAR PRODUCTS—
Naphthalene
Hamburg, 200 brls.

CREAM OF TARTAR—
Bordeaux, 20 cs., 20 brls.
Hamburg, 20 cks.

DEXTRINE—
Hamburg, 700 bgs.

GLUE—
Antwerp, 30 bgs.

MAGNESIUM CHLORIDE—
Hamburg, 300 drms.

PARAFFIN WAX—
New Orleans, 199 sks.

POTASH ALUM—
Hamburg, 66 brls.

RED LEAD—
Genoa, 98 cks.

ROSIN—
New Orleans, 100 brls.

SALT—
Hamburg, 300 bgs.

SOAP—
Catania, 206 cs.
Melbourne, 600 cs.
New Orleans, 160 brls.

SODIUM SULPHATE—
Hamburg, 100 bgs.

STEARINE—
Antwerp, 13 bgs.

SULPHUR—
Catania, 934 pkgs.

TANNING MATERIALS—
Chestnut
Genoa, 70 brls.
Wattle
Natal, 2,550 bgs., 2,365 bls.

TARTARIC ACID—
Genoa, 24 brls.

WAX (*otherwise undescribed*)—
New Orleans, 310 brls.

WHITE LEAD—
Genoa, 98 cks.
Hamburg, 19 cks.

ZINC ASHES—
Natal, 98 bgs.

ZINC OXIDE—
Antwerp, 16 brls.

GOOLE.

Week ending July 14.

Algoa Bay, 10 c., £96.; Amsterdam, 120 t., £2,050.; Havana, 1 t., £28.; Hong Kong, 4 t. 3 c., £131.; Hankow, 6 t. 5 c., £194.; Karachi, 1 t. 5 c., £33.; Melbourne, 1 t., £29.; Shanghai, 5 t., £135.; Viborg, 10 t., £62.

CITRIC ACID—
Barcelona, 1 t. 10 c., £257.

COAL TAR PRODUCTS—
Aniline Oil
Amsterdam, 1 t., £95.
Carbolic Acid
Adelaide, 1 c., £10.
Fremantle, 18 c., £30.
Hamburg, 15 t. 10 c., £2,253.
Creosote
New York, 8 c., £14.
Stockholm, 1 t. 18 c., £44.
Creosote Oil
Smyrna, 93 t. 15 c., £1,606.
Naphthalene
Sydney, 2 t., £23.
Pitch
Demerara, 3 t. 7 c., £36.
Rouen, 506 t. 3 c., £3,416.
Pyridine
Hamburg, 2 t. 3 c., £250.
Tar
Bombay, 1 t., £20.
Oporto, 4 t., £46.
Porto Novo, 1 c., £10.
Unspecified
Puerto Barrios, 4 c., £14.

COBALT OXIDE—
Sydney, 7 c., £87.

COPPER SULPHATE—
Auckland, 5 c., £7.; Bordeaux, 12 t. 17 c., £312.; Buenos Ayres, 17 t. 9 c., £423.; Bombay, 3 t., £77.; Calcutta, 7 t. 10 c., £195.; Fremantle, 1 c., £2.; Monte Video, 31 t. 14 c., £825.; Melbourne, 1 t., £27.; Puerto Alegre, 22 t., £548.; Sydney, 1 t., £26.; Wellington, 1 t., £26.; Bourgas, 19 c., £24.

CREAM OF TARTAR—
Newcastle, 3 t. 15 c., £382.

DISINFECTANTS (*otherwise undes.*)
Antwerp, 3 t. 11 c., £96.; Boston, 12 t. 1 c., £488.; Buenos Ayres, 83 t., £4,346.; Colombo, 1 t. 4 c., £47.; Demerara, 19 c., £17.; Monte Video, 4 t. 11 c., £229.; Madras, 1 t. 1 c., £37.; Montreal, 2 t., £83.; New York, 12 c., £29.; Pt. Harcourt, 1 t. 13 c., £83.; St. Johns (N.F.), 4 t. 10 c., £50.; Singapore, 1 t. 14 c., £30.; Villagarcia, 6 t. 10 c., £38.

DYESTUFFS (**ARTIFICIAL**)—
Alizarine
New York, 12 c., £254.
Santos, 4 c., £218.
Unspecified
Alexandria, 2 t., £353.; Barcelona, 3 c., £71.; Lyttleton, 1 t. 10 c., £471.; Melbourne, 17 c., £234.; Montreal, 2 c., £25.; Oporto, 2 c., £60.; Penang, 1 c., £35.; Rio de Janeiro, 8 c., £132.; Sydney, 3 c., £81.; Singapore, 1 c., £28.

DYESTUFFS (NATURAL)—
Orchil
New York, 1 t. 7 c., £121.

ESSENTIAL OILS (SYNTHETIC)—
Kobe, 1 t. 7 c., £728.

GLYCERINE—
Acajutla, 3 c., £16.; Copenhagen, 3 t., £214.; Cape Town, 100 t., £5,050.; Salvador, 3 c., £14.; Stockholm, 2 t., £158.; Yokohama, 34 t. 5 c., £2,694.

IODOFORM—
Sekondi, 1 qr., £13.

LEAD ARSENATE—
Paita, 9 c., £56.

LEAD NITRATE—
Sydney, 1 t., £4.

MAGNESIA—
Melbourne, 1 t. 7 c., £22.

MAGNESIUM CARBONATE—
Calcutta, 3 c., £16.

MAGNESIUM SULPHATE—
Bermuda, 56 lb., £2.; Bombay, 1 c., £2.; Curacao, 2 c., £3.; Duala, 56 lb., £1; Grand Bassam, 1 c., £1.; Lagos, 10½ c., £16.; Valparaiso, 4 c., £4.; Warri, 1 c., £1.; Winnebah, 56 lb., £1.

NICKEL SALTS (*otherwise undes.*)—
Karachi, 6 c., £12.

NICKEL SULPHATE—
Melbourne, 5 c., £11.

PITCH (*otherwise undescribed*)—
Genoa, 24 t. 5 c., £482.

PLATING SALTS (*otherwise undes.*)
Barcelona, 2 c., £36.

POTASSIUM BICHROMATE—
Constantinople, 12 c., £30.; Norrkoping, 1 t. 9 c., £74.; Pasages, 1 t. 15 c., £83.; Santos, 1 t. 18 c., £99.

POTASSIUM IODIDE—
Opobo, 1 c., £117.
Pt. Harcourt, 560 lb., £537.

SALAMMONIAC—
Marseilles, 15 c., £41.

SALTCAKE—
Antwerp, 175 t., £1,050.
Helsingfors, 250 t. 17 c., £1,068.

SHEEP DIP—
Algoa Bay, 9 t., £526.; Adelaide, 6 t., £206.; Buenos Ayres, 56 t. 4 c., £2,100.; Barranquilla, 2 t. 10 c., £130.; Brisbane, 2 t. 10 c., £141.; Lyttleton, 7 t. 14 c., £262.; Mombasa, 10 c., £41.; Napier, 7 t. 14 c., £262.; Panama, 1 t. 1 c., £80.; Puerto Colombia, 7 c., £42.

SULPHURIC ACID—
Maranhao, 15 c., £25.

SUPERPHOSPHATE—
Las Palmas, 15 t. 8 c., £82.

TANNING MATERIALS—
Unspecified
Antwerp, 17 c., £24.; Christiania, 16 t. 9 c., £358.; Helsingfors, 5 t. 10 c., £71.; Montreal, 2 t. 4 c., £40.

TARTARIC ACID—
Newcastle, 12 c., £79.
Rockhampton, 1 t. 5 c., £175.
Sydney, 4 t., £546.

TIN OXIDE—
Lisbon, 1 c., £18.
Sydney, 10 c., £299.

TRICHLORETHYLENE—
Hsin Ho Wharf, 6 c., £17.

VANADIC ACID—
Dunkirk, 2 t. 1 c., £1,598.

WOOD PRESERVATIVE—
Accra, 14 c., £24.; Kobe, 1 t., £60.

ZINC CHLORIDE—
Bombay, 4 t. 6 c., £106.; Calcutta, 2 t. 2 c., £54.; Madras, 6 t. 8 c., £163.; Rio de Janeiro, 1 t., £42.; Rangoon, 18 c., £23.

ZINC OXIDE—
Helsingfors, 4 t. 18 c., £210.
Melbourne, 1 t., £50.

Week ending July 13.

CALCIUM CHLORATE—
Madras, 20 pkgs.

CAUSTIC SODA—
Adelaide, 30 drms.; Algoa Bay, 112 drms.; Auckland, 33 drms.; Bari, 17 drms.; Barranquilla, 25 drms.; Antwerp, 10 drms.; Brisbane, 15 drms.; Callao, 30 drms.; Cape Town, 20 drms.; Cartagena, 50 drms.; Cheribon, 75 pkgs.; Durban, 20 drms.; Copenhagen, 48 drms.; East London, 30 drms.; Freetown, 20 drms.; Frontera, 50 drms.; Haifa, 18 drms.; Funchal, 34 drms.; Hobart, 20 pkgs.; Launceston, 52 pkgs.; Lyttleton, 20 pkgs.; Madras, 200 drms.; Melbourne, 355 drms.; New Plymouth, 52 drms.; Penang, 70 drms.; Pernambuco, 180 drms.; Piraeus, 20 drms.; Pt. Shanghai, 27 cks.

SODIUM SULPHATE—
Durban, 20 pkgs.

SODIUM SULPHIDE—
Algoa Bay, 5 pkgs.
Cape Town, 5 pkgs.

STEARINE—
Shanghai, 307 dble. bgs.

TALLOW—
Calcutta, 56 cks.
Hamburg, 6 pkgs.
Helsingfors, 30 brls.

ZINC DUST—
Hobart, 800 pkgs.

LONDON.

OFFICIAL AMENDMENT.

From Return for week ending April 11, 1923.

Deduct—

AMMONIUM CARBONATE—
Madras, 1 t. 7 c., £213.

Week ending July 11.

ACETIC ACID—
Bombay, 7 cs., £22.
Christchurch, 3 cs., £9.
Malta (F.), 1 ck., £9.
Melbourne, 10 cs., £27.
Wellington, 10 cs., £35.

ACETONE—
Rangoon, 4 drms., £28.

ACETYL SALICYLIC ACID—
Bangkok, 17 cs. (pt.), £21.
Shanghai, 3 cs. (pt.), £14.
Singapore, 1 cs. (pt.), £9.

ALUM—
Singapore, 1 t., £23.

ALUMINIUM SULPHATE—
Rangoon, 2 cs., £6.

AMMONIA—
Antwerp, 20 cs., £105.; Bombay, 27 cs., £48.; C. T'n, 12 cs., £24.; Durban, 13 cs., £32.; E. London 11 cs., £19.; H. Kong, 3 cs., £5.; I. F. State, 2 cs., £36.; Karachi, 19 cs., £33.; Madras, 3 cs., £9.; M.Bay, 2 cs., £5.; Pt. Elizabeth, 13 cs., £31.; Pt. Said, 4 cs., £7.; Rangoon, 1 cs., £6.; Rosario, 20 cs., £56.; Shanghai, 5 cs., £9.

AMMONIA (ANHYDROUS)—
Belawan, 400 cylds., £2,833.
Durban, 35 cylds., £262.
Irish Free State, 6 cylds., £30.

AMMONIUM ACETATE—
Bombay, 4 cs. (pt.), £8.
Cape Town, 4 jars, £5.

AMMONIUM BROMIDE—
Melbourne, 1 cs., £5.

AMMONIUM CARBONATE—
Brussels, 2 t., £77.; Calcutta, 10 c., £83.; Demerara, 1 t., £33.; Galatz, 10 t., £295.; Melbourne, 1 c., £6.; Monte Video, 1 t. 8 c., £84.; Rangoon, 1 t. 16 c., £118.

AMMONIUM CHLORIDE—
Bombay, 4 cs. (pt.), £10.

AMMONIUM NITRATE—
Hong Kong, 4 c., £7.

AMMONIUM SULPHATE—
Barbados, 6 t., £93.; Beira, 5 t. 10 c., £85.; Canton, 5 t., £90.; Demerara, 55 t., £1,223.; Hong Kong, 50 t., £819.; Mauritius, 175 t., £2,713.; Las Palmas, 37 t., £624.; Naples, 79 t., £1,225.

ANTIMONY SULPHIDE—
Bombay, 7 cks., £77.

ARSENIC—
Colombo, 2 brls., £17.; Durban, 100 drms., £290.; Genoa, 16 cks., £265.; Irish Free State, 1 kg., £5.; Kano, 2 t., £28.; Leghorn, 10 cks., £150.

ARSENIC SULPHIDE—
New York, 20 kgs., £112.

BARIUM HYDRATE—
Paris, 50 cks., £221.

BARIUM NITRATE—
Colombo, 1 ck., £10.

BARIUM PEROXIDE—
Genoa, 10 drms., £118.
Sydney, 43 drms., £336.

BARIUM SULPHATE—
Auckland, 1 cs. (pt.), £5.

BARIUM SULPHIDE—
Bombay, 4 cs. (pt.), £9.

BISMUTH CARBONATE—
Bangkok, 17 cs. (pt.), £38.; Christchurch, 1 cs. (pt.), £11.; Melbourne, 2 cs., £144.; Pt. Elizabeth, 1 cs., £64.

BISMUTH SALICYLATE—
Sydney, 11 pkgs. (pt.), £30.

BISMUTH SALTS (*otherwise undes.*)
Auckland, 1 cs. (pt.), £16.
Melbourne, 1 cs. (pt.), £51.
Rangoon, 1 cs., £63.

BISMUTH SUBCARBONATE—
Bangkok, 17 cs. (pt.), £13.

BISMUTH SUBNITRATE—
Montreal, 1 cs., £125.

BITUMEN—
Monte Video, 11 cks., £41.
Rouen, 39 brls., £98.
Singapore, 20 pkgs., £60.

BONE FERTILISER—
Dunkirk, 8 t., £75.
Hamburg, 5 t. 12 c., £13.

BORAX—
Bermuda, 2 c., £6.
Shanghai, 5 c., £8.
Sydney, 1 c., £5.

BORIC ACID—
Auckland, 2 c., £8.

CALCIUM CARBIDE—
Bangkok, 3 c., £5.; Basra, 2 t. 9 c., £71.; Levuka (F.), 10 c., £8.; Sekondi, 4 c., £6.

CALCIUM CHLORIDE—
Las Palmas, 10 drms., £19.

CALCIUM LACTATE—
Sydney, 11 pkgs. (pt.), £6.

CAUSTIC SODA—
Beira, 3 c., £6.
Shanghai, 1 c., £7.

CERIUM OXALATE—
Rangoon, 1 cs. (pt.), £6.

CHEMICALS (*otherwise undescribed*)
Alexandria, 5 cs., £63.; Antwerp, 50 pkgs., £143.; Bangkok, 17 cs. (pt.), £12.; Barbados, 1 cs., £7.; Barranquilla, 5 cks., £7.; Bombay, 6 cs., £13.; Brisbane, 72 pkgs., £124.; Bucharest, 4 pkgs. (pt.), £18.; Hamburg, 193 pkgs., £1,182.; Helsingborg, 3 pkgs., £8.; Helsingborg (F.), 1 pkg., £5.; Irish Free State, 3 pkgs., £5.; Jamaica, 12 pkgs. (pt.), £12.; Karachi, 13 cs., £19.; Lyttleton, 40 pkgs., £68.; Madras, 2 cs. (pt.), £28.; Malta, 2 cks., £6.; Medellin, 3 cks., £7.; Melbourne, 30 pkgs. (pt.), £145.; Otago, 20 pkgs., £40.; Port Alma, 10 pkgs., £26.; Puerto Cabello, 7 pkgs. (pt.), £19.; Rangoon, 3 cs., £22.; Rockhampton, 20 pkgs., £28.; Rotterdam, 255 pkgs., £745.; Shanghai, 7 cs. (pt.), £39.; Singapore, 2 cs., £9.; Swatow, 2 pkgs., £5.; Sydney, 42 pkgs. (pt.), £130.; Tokio, 16 cks., £72.; Townsville, 10 pkgs., £28.

CHRYSOPHANIC ACID—
Calcutta, 1 cs. (pt.), £6.

CITRIC ACID—
Cartagena (Col.), 1 c., £13.; Cape Town (F.), 15 c., £136.; Cape Town, 4 c., £38.; Channel Islands, 1 c., £10.; Durban, 2 c., £21.; Rotterdam, 3 c., £30.

COAL TAR PRODUCTS—
Carbolic Acid
Bombay, 1 cs., £24.; Canton, 2 cs., £12.; Melbourne, 5 drms., £6.; Shanghai, 2 cs., £10.; Sydney, 50 drms., £44.
Creosote
San Francisco, 5 drms., £60.

COAL TAR PRODUCTS—
Creosote Oil
Delagoa Bay, 75 drms., £468.
Naphthalene
Canton, 5 kgs., £8.; Durban, 5 cs., £7.; Sydney, 16 cks., £45.
Pitch
Melbourne, 3 kgs., £5.
Suva, 10 cs., £12.
Pyridine
Durban, 40 drms., £191.
Tar
Durban, 590 drms., £67.

COBALT OXIDE—
Melbourne, 1 cs., £50.
Paris, 9 cs., £574.

COPPER CARBONATE—
Colombo, 1 cs., £11.

COPPER CHLORIDE—
Melbourne, 1 pkg., £12.

COPPER SULPHATE—
Delagoa Bay, 3 c., £20.
Tientsin, 1 cs., £40.

CREAM OF TARTAR—
Barbados, 1 c., £5.; Barranquilla, 1 c., £6.; Calcutta, 2 cs., £5.; Karachi (F.), 1 c., £6.; Pt. Elizabeth, 5 c., £23.; Puerto Cabello, 1 c., £6.

DISINFECTANTS (*otherwise undes.*)
Aden, 1 t., £11.; Alexandria, 1 t. 3 c., £55.; Auckland, 11 c., £112.; Boulogne, 3 c., £9.; Calcutta, 2 t. 6 c., £110.; Christchurch, 2 c., £12.; Durban, 17 c., £59.; East London, 2 t. 6 c., £180.; Invercargill, 3 c., £40.; Jamaica, 2 t. 15 c., £74.; La Union, 1 t. 4 c., £41.; Penang, 9 c., £19.; Pt. Elizabeth, 6 t. 9 c., £154.; Pt. Swettenham, 3 c., £7.; Shanghai, 5 t., £250.; Singapore, 1 t. 12 c., £58.; Toronto, 1 c., £6.

DYESTUFFS (ARTIFICIAL)—
Nigrosine
Delagoa Bay, 2 kgs., £15.
Unspecified
Bombay, 1 cs. (pt.), £6.; Boulogne, 35 kgs., £442.; Brisbane, 2 cs. (pt.), £85.; Melbourne, 1 kg., 3 cs. (pt.), £19.; New York, 1 cs., £8.; Sydney, 1 cs., £11.

ETHER—
Jamaica, 10 cs., 4 cs. (pt.), £23.
Toronto, qnty.
Winnipeg, 2 cs., £19.

ETHYL CHLORIDE—
Rangoon, 1 cs. (pt.), £6.

FERTILISERS (*otherwise undes.*)—
Gothenburg, 1 t., £25.
New York (F.), 10 t., £80.

FORMALDEHYDE—
Madras, 2 crts., £16.

GALLIC ACID—
Sydney, 1 cs., £38.

GLYCERINE—
Amoy, 1 c., £6.; Cartagena (Col.), 3 c., £18.; La Guaira, 2 c., £11.

HEXAMINE—
Melbourne, 1 cs. (pt.), £6.
Sydney (F.), 1 cs., £23.

HYDROBROMIC ACID—
Sydney, 7 pkgs. (pt.), £16.

HYDROCHLORIC ACID—
Alexandria, 3 c., £14.
Pt. Elizabeth, 4 c., £12.

HYROFLUORIC ACID—
Hong Kong, 4 cs., £27.
Pt. Elizabeth, 3 cs., £18.

HYDROGEN PEROXIDE—
Alexandria, 5 cs., £32.
Gibraltar, 2 cs., £13.
Melbourne, 2 cs., £7.

HYPOPHOSPHOROUS ACID—
Sydney, 2 cs., £16.

IODIDES (*otherwise undescribed*)—
Yokohama, 9 cs., £783.

IODINE—
Auckland, 1 cs. (pt.), £26.
Melbourne, 2 cs. (pt.), £88.

IODINE (RESUBLIMED)—
Canton, 1 cs. (pt.), £14.

IRON AMMONIUM CITRATE—
Amsterdam, 5 cs. (pt.), £96.
Buenos Ayres, 2 cs., £16.
Sydney, 11 pkgs. (pt.), £7.

IRON IODIDE—
Shanghai, 1 cs. (pt.), €5.

KIESELGUHR—
Rio de Janeiro (F.), 1 t. 1 c., £19.
Santos (F.), 12 c., €10.

LACTIC ACID—
Mossel Bay (F.), 10 cks., £76.

LEAD CHROMATE—
Malmo, 3 cks., £65.

LEAD NITRATE—
Calcutta, 2 cks., £25.

MAGNESIA—
Antwerp, 20 cs., £48.; Bombay, 4 cs., €10.; Irish Free State, 4 cs., €15.; Napier, 6 cs., €14.; Rio de Janeiro, 2 cs., €13.; Stockholm, 2 cs. (pt.), €17.; Sydney, 8 cs., £20.

MAGNESIA (CALCINED)—
Buenos Ayres, 6 cks.,. £21.
Puerto Cabello, 1 cs., £10.

MAGNESIUM CARBONATE—
Buenos Ayres, 2 cs., £9.
Calcutta, 1 cs., £6.
La Guaira, 2 cs., £9.
Melbourne, 5 cs., £18.
Rio de Janeiro, 4 cs., £16.

MAGNESIUM CITRATE—
Rangoon, 2 cs., £14.

MAGNESIUM SULPHATE—
Bermuda, 4 c., £5.; Bombay, 3 c., £5.; Durban, 10 c., £11.; Irish Free State, 2 c., £5.; Jamaica, 10 c., £7.; Karachi, 2 c., £6.; La Guaira, 10 c., £8.; Melbourne, 2 c., £5.; Newcastle, 2 t. 10 c., £59.; New York, 5 c., £8.; Panama, 5 c., £7.; Sydney, 5 t. 2 c., £121.; Toronto, 10 c., £8.

MERCURIALS (*otherwise undes.*)—
Calcutta, 1 cs. (pt.), €6.
Melbourne, 2 cs. (pt.), £15.

MERCURY IODIDE—
Montreal, 1 cs., £69.

METHYL SALICYLATE—
Sydney, 19 pkgs. (pt.), €17.

NITRIC ACID—
Alexandria, 1 c., €7.

OXALIC ACID—
Auckland, 1 ck., £11.

PHOSPHORIC ACID—
Melbourne, 5 cs., £19.

PHOSPHORUS—
Havana, 50 cs., £237.

PHOSPHORUS (AMORPHOUS)—
Havana, 8 cs., £94.

POTASSIUM BROMIDE—
Sydney, 5 cs., £23.

POTASSIUM CARBONATE—
Hong Kong, 5 cs., £18.

POTASSIUM CHLORATE—
Barranquilla, 2 cks., £5.
Cartagena, 3 cks., £8.

POTASSIUM CITRATE—
Auckland, 1 cs. (pt.), £5.
Bangkok, 17 cs. (pt.), £15.
Melbourne, 1 cs. (pt.), 2 cs., £34.
Sydney, 19 pkgs. (pt.), £61.

POTASSIUM CYANIDE—
Swatow, 1 cs., £9.

POTASSIUM FERRICYANIDE—
Amsterdam, 5 cs. (pt.), £22.

POTASSIUM IODIDE—
Antwerp, 1 cs., £86.; Auckland, 2 cs. (pt.), £63.; Accra, 1 cs., £15.; Bangkok, 17 cs. (pt.), £254.; Brussels, 3 cs., £258.; Calcutta, 3 cs., £263.; Melbourne, 1 cs., £88.; Montreal, 4 cs., £313.; Naples, 4 cs., £173.; Puerto Colombia, 1 cs. (pt.), £14.; Rangoon, 4 cs., £183.; Sydney, 30 pkgs. (pt.), 1 cs., £198.

POTASSIUM PERMANGANATE—
Melbourne (F.), 1 cs., £9.
Pt. Elizabeth, 1 kg., £5.
Sydney, 30 pkgs. (pt.), £183.

POTASSIUM AND SODIUM NITRATE—
Trinidad, 50 t., £750.

PRUSSIAN BLUE—
Shanghai, 1 cs., £8.

ROCHELLE SALTS—
Hong Kong, 3 cs. (pt.), £16.

SALAMMONIAC—
Auckland, 3 cks., £5.; Barranquilla, 1 ck., £5.; Melbourne, 2 cks., £29.; Rio de Janeiro, 4 cks., £39.

SALICYLIC ACID—
Durban, 1 kg., £13.

SALTCAKE—
Kotka, 520 t., £2,600.
Moss, 420 t., £2,100.

SALTPETRE—
Barranquilla, 2 c. £7.; Cartagena (Col.), 5 c., £17.; East London, 5 c., £10.; Invercargill, 10 c., £20.; Sydney, 6 t., £245.

SILVER NITRATE—
East London, 1 cs. (pt.), £12.
Hong Kong, 2 cs. (pt.), £72.

SODA CRYSTALS—
Irish Free State, 5 c., £6.

SODIUM ARSENATE—
Barcelona, 8 cks., £51.
Melbourne, 1 t., £50.

SODIUM BICARBONATE—
Cartagena (Col.), 1 t., £20.; Corinto, 4 c., £7.; Managna, 3 c. €5.; Melbourne, 5 c., £10.; Nassau, 3 c., £5.; Panama, 5 c., £9.; Rangoon, 1 c., £6.

SODIUM BISULPHITE—
Paris, 1 t., £26.; Penang, 2 t., £40.; Sourabaya, 2 t. 10 c., £50.

SODIUM BROMIDE—
Melbourne, 2 cs., £10.

SODIUM CARBONATE—
Calcutta, 1 c., £5.
Sydney, 7 pkgs. (pt.), €7.

SODIUM CITRATE—
Calcutta, 1 ck., £6.
Melbourne, 1 cs. (pt.), £6.

SODIUM CYANIDE—
Channel Islands, 4 pkgs., £17.

SODIUM GLYCEROPHOSPHATE—
Christiania, 6 pkgs., £33.

SODIUM HYPOSULPHITE—
Durban, 4 c., £5.
Hong Kong, 2 t. 6 c., €78.
Singapore, 2 cs., £16.

SODIUM IODIDE—
Calcutta, 1 cs. (pt.), £19.
Naples, 4 cs., £197.

SODIUM NITRATE—
Trinidad (F.), 100 t., £1,515.

SODIUM OXALATE—
Colombo, 1 c., £8.

SODIUM PRUSSIATE—
Rio de Janeiro, 1 t., £74.

SODIUM SALICYLATE—
Auckland, 2 cs. (pt.), £16.
Melbourne, 3 cs., £44.
Sydney, 1 cs., 19 pkgs. (pt.), £27.

SODIUM SALTS (*otherwise undes.*)
Calcutta, 2 cks. (pt.), £17.

SODIUM SILICATE—
Huatsuka, 8 c., £7.
Pt. Elizabeth, 12 c., £18.

SODIUM SULPHATE—
Cartagena, 1 t. 10 c., £21.
Shanghai, 15 c., £17.
Swatow, 1 c., £6.

SODIUM SULPHITE—
Antwerp, 10 c., £15.

SODIUM TARTRATE—
Calcutta, 3 cs., £15.
Melbourne, 5 cs., £27.
Montreal, 1 t., £75.

STRONTIUM CARBONATE—
Colombo, 1 ck., £11.

SULPHUR (FLOWERS)—
Cape Town, 9 t. 19 c., £142.

SULPHURIC ACID—
Alexandria, 2 c., £5.; Accra, 14 c., £33.; Dar-es-Salaam, 11 c., £14.; Pt. Elizabeth, 5 c., £12.; Sekondi, 2 t. 6 c., £57.; Singapore, 10 t. 5 c., £170.

TARTARIC ACID—
Barranquilla, 1 c., £9.; Christiania (F.), 10 c., £69.; Irish Free State, 1 c., £8.; Medellin, 1 c., £8.; Melbourne, 5 c., £35.; New York (F.), 10 t., £1,300.; Pt. Elizabeth, 1 c., £8.; Puerto Cabello, 1 c., £9.; Rangoon, 3 c., £34.

TITANIUM POTASSIUM OXALATE—
Cape Town (F.), 1 kg., £8.

TURPENTINE—
Singapore, 2 drms., £7.

ZINC OXIDE—
Brussels, 1 ck., £6.; Copenhagen, 80 cks., £308.; Malmo, 30 cks., £127.; New York, 10 cs., £55.; Melbourne, 1 ck., £6.; Punta Arenas, 1 ck., £5.

Week ending July 14.

BEESWAX—
Brisbane, 1 t.
Melbourne, 10 c.
Sydney, 2 c.

CARNAUBA WAX—
Trieste, 1 t.

FULLER'S EARTH—
Alexandria, 28 t.
Antwerp, 6 t.
Christiania, 25 t.
Los Angeles, 20 t.
New York, 55 t.
Rotterdam, 106 t.

GLUE, SIZE, AND GELATINE—
Delagoa Bay, 3 c.; Drammen, 10 c.; Durban, 2 c.; East London, 3 c.; Fremantle, 13 c.; Hong Kong, 6 t. 14 c.; Lyttleton, 2 t.; Montreal, 1 c.; Paris, 12 t. 1 c.; Pt. Elizabeth, 2 c.; Pt. Swettenham, 1 c.; Rangoon, 10 c.; Shanghai, 2 c.; Singapore, 1 c.; Sourabaya, 1 t. 10 c.; Stockholm, 6 c.; Wiborg, 19 c.; Yokohama, 2 c.

MINERAL WAX—
Delagoa Bay, 6 t.
Sydney, 1 t.

PARAFFIN WAX—
Antwerp, 4 t. 10 c.

PLUMBAGO—
Alexandria, 12 c.; Bilbao, 10 t. 17 c.; Boulogne, 1 t. 15 c.; Brussels, 5 c.; Delagoa Bay, 9 c.; Kilindini, 2 c.; Lisbon, 10 c.; Pt. Said, 1 t.; Rio de Janeiro, 2 c.; Valparaiso, 1 t. 16 c.

QUININE—
Bombay, 2,036 oz.; Calcutta, 5,012 oz.; Fremantle, 1,000 oz.; Madras, 100 oz.; Melbourne, 2,400 oz.; Piraeus, 1,456 oz.; Pt. Elizabeth, 7,730 oz.; Sydney, 1,000 oz.; Wellington, 74 oz.

ROSIN—
Sekondi, 4 c.

SALT—
Amsterdam, 6 c.; Durban, 2 c.; Fiji Islands, 1 t. 5 c.; Fremantle, 16 c.; Helsingborg, 12 c.; Invercargill, 4 t. 1 c.; Iquique, 3 c.; Kilia, 10 c.; Labrador, 2 c.; Malmo, 6 c.; Melbourne, 1 c.; Pt. Elizabeth, 9 c.; Pt. Sudan, 16 c.; St. Lucia, 7 c.; St. Helena, 10 c.; Stockholm, 4 c.; Suez, 13 c.; Shanghai, 2 c.; Trinidad, 15 c.

SHELLAC—
Melbourne, 6 c.

SOAP—
Antwerp, 14 c.; Bangkok, 2 t. 7 c.; Bermuda, 1 c.; Bombay, 1 t. 6 c.; Boulogne, 2 c.; Brussels, 4 c.; Buenos Ayres, 9 c.; Calcutta, 5 c.; Christchurch, 8 c.; Colombo, 13 c.; Demerara, 2 c.; Durban, 1 c.; Fiji Islands, 1 c.; Grand Bassam, 1 t.; Half Assinie, 2 t.; Harlingen, 1 c.; Hong Kong, 2 c.; Irish Free State, 12 c.; Iquique, 8 c., Jamaica, 30 t. 11 c.; Karachi, 2 c.; Kilindini, 2 c.; Lagos, 4 t. 5 c.; Lome, 10 c.; Malta, 5 c.; Manilla, 1 c.; Melbourne, 8 c.; Monte Video, 9 c.; Opobo, 19 t. 12 c.; Penang, 7 c.; Pt. Elizabeth, 1 c.; Pt. Harcourt, 7 t. 4 c.; Pt. Said, 5 c.; Pt. Sudan, 2 c.; Punta Arenas, 2 c.; Rangoon, 2 c.; Rio de Janeiro, 3 c.; Rotterdam, 2 c.; Sierra Leone, 1 t.; St. Helena, 2 c.; Sekondi, 3 t. 14 c.; Shanghai, 2 c. Singapore, 1 c.; Tientsin, 1 c.; Tokio, 3 c.; Toronto, 3 t. 16 c.; Trinidad, 5 t. 18 c.

SOAP—
Valparaiso, 1 t.
Warri, 7 c.
Wellington, 1 t. 5 c.

SPERMACETTI WAX—
Paris, 1 t.

STEARINE—
Irish Free State, 1 t.

TALLOW—
Dusseldorf, 20 t. 4 c.; Ghent, 13 t. 4 c.; Hamburg, 20 t. 7 c.; Harlingen, 2 t. 10 c.; Sekondi, 2 c.

WHITE LEAD—
Auckland, £680.; Bluff, £50.; Brisbane, £95.; Calcutta, £165.; Christchurch, £121.; Dominica, £16.; Dunedin, £9.; Durban, £180.; East London, £32.; Fiji Islands, £98.; Hong Kong, £22.; Invercargill, £143.; Irish Free State, £70.; Melbourne, £1,051.; Napier, £246.; Oamaru, £25.; Piraeus, £50.; Rangoon, £20.; Shanghai, £80.; Sydney, £1,133.; Trinidad, £84.; Wellington, £158.

ZINC ASHES—
Antwerp, 6 t.

MANCHESTER.

Week ending July 12.

ALUM—
Canada, 125 pkgs.
Holland, 35 cks.

CARBON BLACK—
Belgium, 10 cs.

CHEMICALS (*otherwise undescribed*)
Antwerp, 4 cks., 12 kgs.; Belgium, 3 pkgs.; Basle, 12 cks.; Copenhagen, 15 cks.; France, 5 bgs.; Hamburg, 25 cks.

COAL TAR PRODUCTS—
Aniline Oil
Basle, 12 drms.
Naphthalene
New York, 207 bgs.
Tar
Germany, 4 t. 16 c.
Unspecified
France, 432 t. 17 c.

DYESTUFFS (ARTIFICIAL)—
Alizarine
Bombay, 289 kgs.
Unspecified
Melbourne, 2 drms.
Tuticorin, 1 drm.

FERRO MANGANESE—
Antwerp, 95 t.; Baltimore, 800 t.; Hamburg, 50 t.

GELATINE—
Belgium, 16 bgs.
Canada, 10 bgs.

GLUE—
Canada, 20 bgs.
Montreal, 40 bgs.

GLYCERINE—
Holland, 4 drms.

LEAD ACETATE—
France, 15 cks.

MAGNESIUM CHLORIDE—
Bombay, 78 drms.

SALAMMONIAC—
France, 24 cks.

SALT—
Cairo, 1 cs.
Montreal, 1,600 bgs., 1,000 sks.
St. John, 20 t.

SALTCAKE—
Christiania, 500 t.

SOAP—
Bombay, 3 cs., 17 brls.
Cairo, 12 cs.

ZINC SULPHATE—
France, 100 bgs.

PRICES CURRENT.

WEDNESDAY, JULY 18, 1923.

PREPARED BY MESSRS. HIGGINBOTTOM & Co., 21, SPRING GARDENS, MANCHESTER.

The values stated are F.O.R. *at makers' works, but it must be understood that the prices in different localities may vary.*

		£	s.	d.
ACIDS.				
Acetic, 40% and 80%	*cwt.	24/-	&	48/-
Acetic, (Glacial, B.P.) in carboys	*ton	70	0	0
Arsenic, S.G. 2.000	ton	85	0	0
Boric (crystals)	†ton	50	0	0
Citric	lb.	0	1	8¼
Formic, 80/85%	*ton	52	0	0
Hydrofluoric, 59/60%	*lb.	0	0	7½
Lactic, 80%	ton	60	0	0
Muriatic (Tower Salts), 30/32 Tw.	*carboy	0	4	0
Nitric, 80° Tw.	*ton	21	10	0
Oxalic	lb.	0	0	6¼
Phosphoric, 1,500° tech.	*ton	33	0	0
Sulphuric (168°)	*ton	7	10	0
Sulphuric (140°)	*ton	3	15	0
Sulphuric (free from Arsenic, 144°)	*ton	4	10	0
Tannic (commercial)	lb.	0	2	3
Tartaric (crystals)	lb.	0	1	3
COAL TAR PRODUCTS.				
Aniline Oil and Salt	*lb.	0	0	9½
Anthracene, 40/45%, "A"	unit	0	0	4
Benzol, 90%	*gallon	0	1	7
Carbolic Acid (crude 60%)	gallon	0	3	4
Carbolic Acid (crystals 40°)	lb.	0	1	3
Creosote	*gallon	0	0	9½
Cresylic Acid, 95%	*gallon	0	2	6
Naphtha, crude, 30%	*gallon	0	0	9
Naphtha, solvent (90/160)	gallon	0	1	4
Naphthalene, refined	ton	18	10	0
Pitch (f.a.s. Liverpool)	ton	6	15	0
Pyridin	gallon	9	18	0
Tar, crude	ton	4	5	0
Tar, refined	barrel	2	2	6
Toluol	*gallon	0	2	0
Xylol, (pure)	*gallon	0	2	3
GENERAL CHEMICALS.				
Acetone	*ton	120	0	0
Alum, loose lump (delivered)	*ton	12	0	0
Aluminium Sulphate, 17/18%	ton	10	10	0
Aluminium Sulphocyanide	lb.	0	0	7
Aluminoferric (in slabs) 20° Tw.	ton	7	0	0
Ammonia, anhydrous	*lb.	0	1	4
Ammonia, .880	*ton	22	10	0
Ammonia, .920	*ton	14	10	0
Ammonium Carbonate (lump)	lb.	0	0	4
Ammonium Muriate (grey)	†ton	30	0	0
Ammonium Nitrate	ton	35	0	0
Ammonium Phosphate	ton	60	0	0
Ammonium Sulphate, 25¾% delivered	†ton	14	15	0
Ammonium Sulphocyanide, 95%	lb.	0	1	3
Antimony (Golden Sulphide)	lb.	0	0	9
Arsenic (Cornish White)	ton	70	0	0
Barium Carbonate (native), 92/94%	ton	5	15	0
Barium Chlorate	lb.	0	0	8
Barium Chloride (in casks)	ton	15	0	0
Barium Sulphate	ton	£5	to	£7
Barium Sulphocyanide, 95%	lb.	0	0	10½
Bleaching Powder, 35%	*†ton	11	7	6
Bleaching Liquor, 7%	*ton	4	5	0
Calcium Chloride	†ton	5	10	0
Carbon Bisulphide	*ton	28	0	0
Casein (commercial)	ton	80	0	0
China Clay (at Runcorn), in Bulk	ton	50/-	to	90/-
Chromium Acetate (crystals)	lb.	0	0	8
Copper Sulphate	ton	26	0	0
Formaldehyde, 40%	ton	94	0	0
Glycerine (chemically pure, S.G. 1,260)	*ton	85	0	0
Glycerine (crude), 80%	*ton	60	0	0
Iodine	*oz.	0	1	0
Iron Nitrate, 80° Tw.	*ton	6	5	0
Iron Sulphate (copperas), delivered in Bulk	*ton	2	0	0
Iron Sulphide (lumps)	ton	6	0	0
Lead Acetate (white)	ton	40	0	0
Lead Acetate (brown)	ton	42	0	0
Lead Carbonate (White Lead)	ton	44	0	0
Lead Nitrate	ton	42	0	0
Lime Acetate (brown)	*ton	11	0	0
Lime Acetate (grey), 80%	*ton	21	0	0
Lime Bisulphite (S.G. 1,070)	*ton	8	0	0
Lime Superphosphate, 30%	ton	3	15	0
Litharge	ton	37	0	0
Magnesite, Calcined (delivered)	ton	11	0	0
Magnesite, Raw	ton	3	0	0
Magnesium Carbonate (light)	cwt.	2	0	0
Magnesium Chloride (solid)	ton	3	0	0
Magnesium Sulphate (Epsom Salts, coml.)	ton	4	0	0
Magnesium Sulphate, B.P.	ton	6	0	0
Manganese Borate, 85%	ton	112	0	0
Manganese Sulphate, 90%	ton	50	0	0
Methylated Alcohol, 64° (industrial)	gallon	0	2	1
Naphtha (Wood), Solvent	*gallon	0	6	6
Naphtha (Wood), Miscible, 60° p.	gallon	0	6	6
Potassium Bichromate	lb.	0	0	5¾
Potassium Carbonate, 90%	ton	28	0	0
Potassium Chlorate	lb.	0	0	3
Potassium Hydrate (Caustic Potash), 88/90%	ton	29	0	0
Potassium Hydrate (Caustic Potash), 75/80%	ton	26	0	0
Potassium Hydrate (liquid), 50° Bé.	ton	18	0	0
Potassium Chloride 80%	ton	8	10	0
Potassium Nitrate (refined)	ton	32	0	0
Potassium Permanganate (commercial)	lb.	0	0	9¾
Potassium Prussiate (yellow)	lb.	0	1	2¾
Potassium Prussiate (red)	lb.	0	4	0
Potassium Sulphate, 90% (ex ship)	ton	11	10	0
Potassium Sulphocyanide	lb.	0	1	6
Salammoniac, lump (sublimed) 1st & 2nd	cwt.	60/-	&	57/-
Sodium Acetate	ton	24	10	0
Sodium Arsenate, 45%	ton	50	0	0
Sodium Borate (Borax), Crystals	*ton	27	0	0
Sodium Bicarbonate (2 cwt. bags)	†ton	10	10	0
Sodium Bichromate	lb.	0	0	4½
Sodium Carbonate, (Soda-ash), 48%	ton	15	0	0
Sodium Carb. (Alkali), 58% bags	†ton	7	12	6
Sodium Carb. (Soda Crystals), bags, car. pd.	†ton	5	5	0
Sodium Chlorate	lb.	0	0	2¾
Sodium Cyanide (100% basis) for export	lb.	8½d.	to	9d.
Sodium Hydrate (76% C. Soda), f.o.r.	†ton	21	10	0
Sodium Hydrate (70% C. Soda)	†ton	20	0	0
Sodium Hydrate (60% C. Soda)	†ton	19	0	0
Sodium Hydrate (Liquid, 90° Tw.)	†ton	8	10	0
Sodium Hydrate, 77/78% powdered (99%)	†ton	26	0	0
Sodium Hyposulphite (commercial)	†ton	10	0	0
Sodium Hyposulphite (photographic)	ton	14	0	0
Sodium Manganate (basis 25%)	ton	45	0	0
Sodium Nitrate, 96% ref'd, f.o.r. L'pool	ton	13	7	6
Sodium Nitrite, 100% basis	ton	26	10	0
Sodium Perborate	lb.	0	0	11¼
Sodium Phosphate	ton	15	0	0
Sodium Prussiate	lb.	0	0	6¾
Sodium Silicate (glass), Alkaline	†ton	11	5	0
Sodium Silicate (liquid, 140° Tw.)	†ton	9	0	0
Sodium Sulphate (Saltcake)	†ton	4	10	0
Sodium Sulphate (Glauber's Salt)	ton	4	0	0
Sodium Sulphide (conc.), 60/65%	ton	15	0	0
Sodium Sulphide Crystals (casks)	†ton	8	10	0
Sodium Sulphocyanide (liquid)	lb.	0	0	6
Sulphur (Flowers) ex ship, Sicilian	ton	8	5	0
Sulphur (Roll Brimstone)	ton	8	5	0
Sulphur (Texas Gulf)	ton	5	5	0
Tartar Emetic, 43/44%	lb.	0	1	1
Tin Crystals	lb.	0	1	4
Tin Perchloride fused	lb.	0	1	10
Titanous Chloride	lb.	0	1	0
Zinc Chloride (solution, 102° Tw.)	*ton	20	0	0
Zinc Sulphate, Crystals	ton	13	10	0
METALS.				
Aluminium (Ingot Metal 98/99%)	ton	115	0	0
Antimony	ton	30	0	0
Copper	ton	64	12	6
Lead (Chemical Sheet), delivered	cwt.	1	13	0
Lead (Foreign Pig)	ton	24	0	0
Nickel	ton	130	0	0
Silver	oz.	0	2	6⅞
Tin, English Ingots	ton	178	0	0
Zinc (Spelter)	ton	28	17	6
Zinc Dust, 90/92%	ton	50	0	0
OILS.				
Cottonseed	*ton	44	10	0
Linseed, Raw	*ton	45	15	0
Stearine, 115-120° M.P.	ton	48	0	0
Tallow	ton	40	0	0
Turpentine	cwt	3	18	0

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	**19s. 6d.**	**24s.**
Half-yearly (26 numbers)	**10s. 6d.**	**13s.**
Quarterly (13 numbers)	**5s. 6d.**	**7s.**

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."

Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

THE SMOKE ABATEMENT BILL.

ACTING on behalf of the Minister of Health, the Earl of Onslow, on Thursday of last week, introduced into the House of Lords, the long-awaited measure dealing with the abatement of smoke nuisances. It will be remembered that the attempt last year to pass a Bill on similar lines did not meet with success, the second reading proving too great an obstacle. The present Bill is largely the embodiment of the recommendations made by Lord Newton's Committee on smoke abatement. As Parliament is to adjourn on August 2 until November 13 next, it does not appear that there is much hope of getting the Bill through before the end of the year. In many respects, this measure is much more workmanlike than its predecessor of last year, and should command the support of those who are interested in making a more effective attempt to lessen the smoke evil. Among the main features of the Bill as at present constituted are the subsections in Clause I. relating to the amendment of the Public Health Act of 1875. Under these amendments, it is proposed that smoke emitted from factory chimneys in such quantity as to be a nuisance shall be deemed to be a nuisance, whatever its colour; while the expression "smoke" is to include soot, ash, grit, and gritty particles. Added to the list of exempted processes are those of re-heating and annealing, hardening, forging, converting and carburising iron and other metals. To appease public opinion on this latter point, however, provision is made whereby the inclusion of any or all of these processes can be annulled, after five years from the passing of the Bill. A clause of definite interest to the chemical industry is the power proposed to be given to the Minister of Health to extend the list of noxious or offensive gases mentioned in section 27 of the Alkali Works Regulation Act, and to increase the list of works mentioned in the first schedule to that Act. Another important proposal is that which increases the maximum penalty which may be imposed in regard to smoke nuisances from £5. to £50. It has frequently been urged that the fines under the existing law should be increased, and it certainly appears to be necessary to allow more power to those responsible for the administration of the law in this respect. One point which is bound to meet with considerable criticism is that if a person charged can show that he has used the best practicable means for

preventing the nuisance, it will be counted as a defence. There is no mention of bringing private dwelling-houses, which are probably the worst offenders in the matter of atmospheric pollution, inside the scope of the Bill, while the immunity of Government works from proceedings under the present Act is to continue. It is almost certain that amendments on many of these points will be suggested.

COLOUR USERS AND THE DYE AGENTS.

The discussion which took place in the House of Commons last week on the Board of Trade estimates furnished an opportunity for further ventilating the position of the dyeing industry in this country. Primed with facts from interested parties, Lieut.-Commander Kenworthy and Mr. J. Hope-Simpson made an attack on the Government's policy of assisting the dyestuff-manufacturing industry. The former member's remarks were mainly confined to extracts from speeches and quotations from reports, by which he endeavoured to show that the high cost of dyes was responsible for the bad state of the British textile trade. Mr. Hope-Simpson, on the other hand, said that the chief opposition probably came from the dyestuff merchants. In this, he was merely quoting Dr. Clayton, who preceded him in the discussion, with this difference, that whereas Dr. Clayton contended that British interests were vastly more important than the interests of the dealers in German dyes, Mr. Simpson believed the dealers played a very important part in the dyeing industry. The smaller users, he said, resort to the larger merchants and rely on their skill and experience for advice with regard to the dyes they shall use. With the merchant gradually being squeezed out, what, then, was to become of the small user? The fact that the larger concerns in the colour-using industries have been able to present such satisfactory reports during the past few years, even under the handicap of higher-priced dyestuffs, while the small dyers and printers have found it difficult to make ends meet is in a great measure attributable to the lack of scientific control in the works of the latter. The smaller firms had previously been relying on the importers of German dyestuffs for advice and technical assistance, under the impression that he received it gratis. Merchants, however, as a class are not business philanthropists, and it may be assumed that such assistance was paid for in the cost of dyestuffs. But there is no need for the small firm, which cannot afford to employ a works' chemist to suffer for the lack of this indirectly German-subsidised assistance. Efficient organisation in the factory and close attention to detail will greatly help towards economical working, while it is now substantiated that the quality and range of British dyestuffs is increasingly good. There are several ways of replacing the technical assistance previously obtained from the dyestuff merchant, and, considering that the smaller users constitute a large proportion of the dye-using industries, it is rather disastrous if they depend for their very existence upon the advice of a handful of agents for German products.

THE TRADE POSITION.

The general impression created by the trade figures for June, as published in the Board of Trade returns, is not a very favourable one. Comparison with last year is not very satisfactory in view of the rapidly changing conditions at home and abroad, the difficult situation in the Ruhr, the exclusion of the Irish Free State from the returns, and the unsteadiness in price quotations. Exports of British goods in June amounted in value to £62,884,000., comparing very favourably with the total for June, 1922, of £52,146,000. It would, however, be fairer under the circumstances, to make comparison with the previous month, when conditions were very similar to those now prevailing. This reveals a drop in exports amounting to £8,671,000., which is accounted for partly by a reduction in coal exports, but principally in manufactured articles, chiefly textiles. The latter fact is of direct interest to the chemical trade, particularly as imports of raw cotton are again lower by £1,315,000. in June, compared with May. The boom in the exports of chemicals in May largely represented activity on the part of purchasers some two or three months previously, when the indications seemed to point towards an increase in prices of chemical products due to general scarcity. June figures reveal a falling off in many lines, and it remains to be seen whether this depression will continue. The figures for the current month will probably be considerably affected by the strike of dock labourers, so that a general shrinkage both in imports and exports is to be expected. The President of the Board of Trade, Sir P. Lloyd-Greame, speaking in the House of Commons last week, warned the country that he did not anticipate that the present volume of trade as revealed in the recent official statistics would be maintained in the coming months. From information derived from all sources, he was led to believe that orders are not coming in owing to the general uncertainty caused by the failure to obtain settled and stable conditions in Europe. In fact, in all the greater industries of this country, the prospects are nothing like as good as they were last January. If this be the considered opinion of the head of the department directly concerned with British trade, it seems to us that the Government is bound to outline and pursue some definite policy with regard to our defaulting late enemy.

New Stainless Alloy.—It is stated that there has just been produced in Sheffield a new alloy, which has far more valuable properties than any of the existing stainless steels or iron. Further details are not yet available, but it is understood that the new material is going to be applied almost immediately to the manufacture of cutlery, and that it has extremely valuable mechanical properties in the sense that it can be forged whether hot or cold, and rolled very thin.

THE FULLER'S EARTH INDUSTRY.

A MINERAL OF GROWING IMPORTANCE.

By A. Brittain, M.Sc., A.I.C.

FULLER'S earth derives its name from the fact that in earlier days it was used extensively by "fullers" for the cleaning or "fulling" of woollen goods, a purpose for which the material was particularly suitable owing to its property of absorbing grease. At that time the mineral was considered so valuable that its export was prohibited under severe penalties, but owing to the introduction of more effective and cheaper cleansing agents it is now used only to a small extent for this purpose. On the other hand, a new and important demand has been created by its use for bleaching purposes in the constantly expanding mineral and vegetable oil industries.

Sources and Scale of Production.

At the present time the two main producers of fuller's earth are Great Britain and the United States. With the extraordinary development of the petroleum industry in America there has arisen an ever-increasing demand for the earth for bleaching purposes, and as the American earth is specially suitable, it is not surprising that the production in the States has risen from 34,459 tons in 1913 to more than twice that figure in 1922. In 1920 Great Britain produced 28,906 tons, a figure which is slightly less than the total for 1913, but with the introduction of oil refining on the large scale into the country, it is expected that the demand for the earth will be considerably increased. Practically the whole of the fuller's earth produced in this country comes from Reigate and Nutfield, in Surrey, and also from Somerset, deposits being worked at a number of localities in the vicinity of Bath. Deposits of the earth are also found at other places throughout the country, but these are small and of little or no commercial importance.

Characteristics of Fuller's Earth.

Fuller's earths are clay-like materials, usually non-plastic, and of a greyish, yellowish, greenish, or bluish colour, although in the trade only two main qualities are recognised —viz., yellow earth and blue earth. The mineral has a specific gravity varying from 1.7 to 2.4, is greasy to the touch, and adheres but slightly to the tongue. When fused it gives a porous slag which melts eventually to a white glass. The properties that make fuller's earth commercially valuable are its power of absorbing grease, and its affinity for the colouring matter contained in oils, fats, and waxes, and it is by these two properties that the earths have been characterised, rather than by their chemical composition, which, as will be shown, is very indefinite and differs widely from one deposit to another. The earths have been described as consisting essentially of hydrated silicates of aluminium, with varying amounts of impurities such as oxide of iron, lime, magnesia, and alkalies. The following analyses show the composition of typical earths found in Great Britain :—

Analyses of British Fuller's Earths.

	Nutfield Earth.	Midford Blue Earth.	Midford Yellow Earth.	Woburn Blue Earth.	Woburn Yellowish Earth.	Frongoch Earth	Reigate Earth.
Silica	58·66	54·0	59·3	60·00	56·9	63·25	53·00
Alumina	17·33	18·6	20·8	15·2	15·7	19·25	10·00
Ferric oxide	7·21	3·9	4·2	7·8	9·5	9·14	9·75

Total	100·00	99·7	99·9	99·9	99·9	100·00	100·00

A study of the chemical composition of these earths shows that although they consist mainly of a series of hydrated aluminium silicates, yet the various samples contain different members of the series, or the same members in different proportions. This variation is seen in the varying ratios of silica, alumina, and water. The combined water in fuller's earth varies from 24 per cent. to 3.6 per cent., whilst an earth with excellent bleaching and grease absorption properties has been reported carrying as little as 0.6 per cent.

The Origin of Fuller's Earth.

The origin of fuller's earth and its relation to the clays is still very much a matter of speculation. It is well known that the decomposition of felspar results in the formation of crystalline aluminium silicates such as are found in ordinary clays, whilst it is believed, although definite proof is still wanting, that the decomposition of hornblendes and augites results in the production of the amorphous aluminium silicates such as are found in fuller's earth. This view is supported by the fact that the amount of magnesia present in the earth is always pronounced and averages much higher than in ordinary clays.

Practically all workable deposits of the earth are of secondary origin, having been redeposited in sedimentary series, and the suggestion has been put forward that fuller's earth represents a true chemical precipitate. If this is so, it would account for its occurrence as an extremely uniform and fine-grained deposit, interbedded with coarse sands, sandy limestones, and highly calcareous limestones. When examined under the microscope, it is seen to be composed partly of amorphous and partly of crystalline matter. The amorphous constituent is probably closely similar to ordinary rock clay in composition, consisting of hydrated aluminium silicates, with mineral matter containing alkalies, iron, and other oxides. The crystalline bodies present include free silica and silicates and various mineral substances, some of which are detrital. The grey-blue colour of fresh fuller's earth is due to the presence of a series of hydrated silicates of aluminium, iron, and potassium. The oxidation of such compounds by weathering, and by the action of percolating water, accounts for the fact that the upper layers of deposits are usually brownish yellow, whereas the unoxidised lower layers are greyish blue.

Preparation of Fuller's Earth.

Fuller's earth is either mined or quarried, the procedure depending on the depth and nature of the overburden. The actual depth of overburden that can profitably be removed depends on its nature and the thickness and quality of the mineral underneath. In Surrey the deposit is both mined and quarried, while in Somerset, where the deposit carries about 40ft. of overburden, the entire production is mined. The earth itself, which usually has a hard smooth surface, although occasionally it is found as a soft friable deposit, is easily dug with pick and shovel. After removal from the quarry or mine, the material is conveyed to the mill for treatment, which is very simple and consists in drying to remove the hygroscopic moisture only, grinding the dried earth, and finally sieving the ground material to the desired sizes. The raw earth is first passed through a crusher, where the lumps are broken down into small pieces to facilitate drying. In some instances the raw earth is stored in large bins, and air-dried, but it is more usual to pass the material direct to the crusher. The crushed earth is then dried, care being taken not to drive off any of the combined water, as for some purpose this would have a deleterious effect. The driers vary somewhat from works to works, but they usually take the form of large rotating cylinders 40-60ft. long and about 6ft. in diameter. These cylinders are set at a slight angle and rotate slowly, the material being lifted up continuously and cascaded down again by horizontal plates attached to the inside of the cylinder and parallel to the axis of rotation. The heating, which is external, is applied either at the end where the wet earth enters, or at the opposite end where the dry material is discharged.

If the fuller's earth is intended to be used for the clarifying of mineral oils, close attention to temperature regulation is not necessary, since in this case the elimination of part of the combined water is not harmful In an oil refinery the earth is usually heated to 250-300° C., or even higher, in order to drive off the combined water, but it must be then used immediately, as otherwise, on exposure to the atmosphere, the earth rapidly reabsorbs its combined water again. When intended for the treatment of edible oils, however, the earth should not be overheated, as the removal of the combined water is supposed to be detrimental, this being especially the case with the English earths, although American earths are not so affected. To prevent any overheating during drying, the earth is sometimes passed through tunnel driers through which hot air is circulated, or it may be treated in special rotary driers capable of close temperature regulation

After drying, the earth is sieved or bolted into sizes depending on the use for which it is intended. If for use in the petroleum industry, the material is placed on the market as 15 to 30 mesh, 30 to 60 mesh, and 60 to 90 mesh, the coarse sizes being mostly in demand. In some of the American mills, where the entire production is applied to the refining of petroleum oils, the very fine material has to be dumped

for lack of a market. In these cases the mills are adjusted to suit the particular class of earth being treated, in order to give a maximum yield of the coarse particles. For edible oils, however, a greater degree of fineness is necessary—usually 100-120 mesh,—although there should not be an excess of very fine material, as this would cause caking and make filtration difficult and unsatisfactory. The English earth can be ground to pass 120 mesh, but the average American material cannot be produced finer than about 100 mesh without introducing an excess of very fine particles.

Applications of Fuller's Earth.

As already stated, the demand for fuller's earth for removing the natural grease from wool has declined to quite small proportions, but many other new uses have been found for it, so that the amount produced is greater than it has ever been previously. Amongst its minor applications might be mentioned its use as a carrier for certain pigments, as a filler for paper, for medicinal and toilet purposes, and, as an ingredient of some soaps; in India, where the mineral is obtained in small quantities in many localities, it is used for the washing of clothes. It also constitutes the principle part of the various edible earths which are sold in the bazaars, the earth-eating habit being prevalent throughout India, Burma, and the Shan States. It is used in small quantities for many other purposes, but the bulk of the earth produced to-day is used for the clarification and decolourisation of many kinds of oils and waxes.

In the petroleum industry large quantities of the earth are used for the final bleaching of paraffin wax for the production of the snow-white article of commerce, and it is also employed for the treatment of various kinds of lubricating oils, in order to improve the colour, by removing the asphaltic colouring matter present. Provided that the bleaching qualities of fuller's earth are good for use in the petroleum industry, its other properties are of minor importance, but an earth intended for the refining of edible oils has to be carefully selected, and should comply with the following requirements:—

(1) It shall bleach well, and the oil shall not revert to its original colour.
(2) It shall filter well and not cake badly.
(3) It shall leave no permanent disagreeable "earthy" taste or odour.
(4) The amount of oil retained in the earth shall be small.
(5) It shall not cause spontaneous ignition of the oil either in the filter press or on the waste heaps.

Superiority of the English Earths for Refining Edible Oils.

The English earth has the reputation of fulfilling these requirements more completely than that produced elsewhere, and many American refiners prefer them to the earths produced in their own country. The undesirable "earthy" taste or odour which some earths impart to edible oils is not now regarded as a serious objection to its use for refining these oils, since it has been found that the odour and taste can be easily removed by blowing dry steam through the refined oil which has been heated to a temperature of somewhat above 100° C. On the other hand, the oxidising action of the earth has proved a serious drawback when thus employed. During the filtration of the oil after treatment with the earth, the refiner naturally endeavours to recover as much as possible of the oil from the cake of earth in the press, and to accomplish this it is usual to blow with air. Owing, however, to the rapid rate at which some fuller's earths promote oxidation, the oil remaining in the earth is liable to, and often does, take fire by spontaneous ignition, which results in no small inconvenience and loss. In this respect, again, English earths are better than American, and it is interesting to note that the United States Government authorised the removal of all restrictions on the importation of the mineral at the beginning of 1919.

The Nature of Fuller's Earth.

The properties possessed by a fuller's earth depend on the particular member or members of the series of hydrated aluminium silicates which compose it, and the proportions in which they are present. Examples of these silicates, which vary widely in composition, are quoted below:—

Mineral.	Formula.	Composition		
		Silica.	Alumina.	Water.
Pyrophyllite	Al_2O_3, $4SiO_2.H_2O$ ..	64.2 ..	30.3 ..	5.0
Rectorite	Al_2O_3, $2SiO_2.H_2O$ ..	50.0 ..	42.5 ..	7.5
Montmorillonite....	Al_2O_3, $3SiO_2.3H_2O$ ..	53.7 ..	30.3 ..	16.0
Smectite	Al_2O_3, $7SiO_2.12H_2O$ ..	57.0 ..	13.8 ..	29.2

Since fuller's earth consists of a mixture of different members of such a series, it is obvious that no definite chemical composition can be assigned to it, but that this will, apart from its impurities, vary from earth to earth. These silicates, however, have one particular property in common—they are all amorphous or non-crystalline bodies which possess a colloidal structure, a colloid being defined as a substance which, when taken up with water, goes into solution, but which will not pass through a parchment membrane as a substance in true solution would do. It is to the presence of of this colloidal material, which has the power of absorbing organic colouring matter present in oils and fats, that the bleaching properties of fuller's earth are attributed.

Colloid-content and Colour-absorbing Powers.

It is well established that many clays, artificial aluminas and silicas, and a considerable number of finely powdered minerals possess decolourising properties to a more or less pronounced extent. The cause of this colour-absorbing property of powdered minerals, and especially of fuller's earth, presents a problem which has yet to be solved, almost every writer having advanced a different explanation to account for it. In view of the known facts, however, it is improbable that the action is a chemical one, and it appears more likely that it is due to the mechanical entanglement of the colouring matters in the "colloidal" portion of the earth. Colloids possess the property of being rapidly stained by organic colouring matters, which they firmly hold in an insoluble form known in the dyeing industry as a "lake." A very familiar example of this is the use of alumina as a mordant in cotton printing. Thus the well-known dyestuff, Turkey Red, is fixed on cloth as a complex lake in which alizarin—the colouring matter—is associated with alumina and calcium.

The Variations in the Bleaching Powers of the Earths.

Fuller's earths differ widely in their action on the colouring matters present in oils and fats, and an earth which will bleach one kind of material will be ineffective towards another. All colouring matters are not absorbed by an earth to the same degree, while different earths vary in their power of absorbing the same colouring matters. A possible explanation of the variation in the bleaching powers of various earths is as follows: Colloidal materials can absorb certain salts, or at least the basic or metallic portions of these salts. This property is also possessed by certain amorphous substances having a fine porous structure, such as charcoal and bone black. These absorbent materials have a selective action upon salts, those portions of an unlike chemical nature only being attracted and absorbed. In view of the partial colloidal nature of fuller's earth, it seems reasonable to expect that the same selective absorbing action would be exerted, and this would vary according to whether the earth is more or less acidic in nature. This latter property is dependent on the composition, the earths carrying the greatest proportion of the acidic oxide of silica, SiO_2 naturally possessing the greatest acidity. Moreover, substances usually submitted to bleaching by fuller's earth contain several colouring matters having different chemical properties, and consequently showing a difference in acidity or basicity. Such being the case, the earth used in bleaching extracts them in proportion to their acidic or basic properties. This would account for the variation in bleaching powers, since the minerals comprising the earths have a preference for different classes of organic colours. Thus, earths which efficiently decolourise vegetable oils containing one type of organic colouring matter, are quite useless for mineral oils, which would contain colouring matters of quite a different nature.

Effects of Heat Treatment.

The bleaching properties of fuller's earth are dependent to some extent on the treatment that it has received before use. Thus, earths which have been heated to moderately high temperatures show a falling-off in their colour-absorbing properties, due to the fact that the earth tends to lose its colloidal structure when heated above 150° C. It is customary, however, when bleaching with the earth, to heat-up the material, by which means it is claimed that an increased bleaching action is obtained. This effect is not due to a stimulation of the inherent bleaching properties of the earth, but to the reduction in the viscosity of the material, and also to the expulsion of air from the surfaces and pores of the absorbing particles, whereby a more intimate contact of the earth and the material to be bleached is obtained.

Although information regarding the relationship between the composition of fuller's earth and the class of colouring matters which it removes most efficiently is at present very meagre, once a well-defined relationship is established it ought to be possible to predict from an analysis the value of an earth and the class of work for which it is best suited. Further, such a thought suggests the possibility of producing a bleaching agent capable of doing the work of fuller's earth, possibly either by chemically treating certain clays and minerals which already possess a certain bleaching power, or by impregnating them with some colloidal matter such as is found in fuller's earth.

SULPHUR IN PORTLAND CEMENT.*

HARMFUL ONLY IN HIGH PERCENTAGES.

SPECIFICATIONS for cement limit the allowable proportion of sulphur (as SO_3), and the question not infrequently arises as to whether cement should be condemned on account of the quantity of SO_3 present. The British Standard specification states that it shall not exceed 2.75 per cent. Manufacturers of cement add gypsum during the process of manufacture, the amount so added depending to a certain extent upon the season of the year and the setting-time required.

The object of the present experiments was to determine the effect, on the strength and soundness of cement, of varying the sulphur-content by the addition of gypsum; also its effect on steel embedded in the cement. The experiments have been carried out in the University of Birmingham, with cements specially made for the purpose. No attempt was made to produce a commercial cement that would satisfy the British Standard specification in all details. Starting with a clinker containing about 2.5 per cent. sulphur (as SO_3), other cements were made by the addition of proportions of gypsum, ranging from 1 to 10 per cent. Thus the percentage of sulphur was approximately as follows:—

Cement Sample No.	Gypsum Added.	SO_3.	Cement Sample No.	Gypsum Added.	SO_3.
	Per Cent.	Per Cent.		Per Cent.	Per Cent.
1	0	2.5	7	6	5.0
2	1	2.9	8	7	5.4
3	2	3.4	9	8	5.8
4	3	3.8	10	9	6.1
5	4	4.2	11	10	6.5
6	5	4.6			

With these special cements five types of specimens were made, and the following tests and observations were carried out:—(*a*) Le Chatelier tests for soundness; (*b*) Tensile strength: neat cement; (*c*) Tensile strength: cement and sand (1 to 3); (*d*) Compression strength tests on 4-in. concrete cubes; (*e*) The effect of sulphur on steel embedded in concrete cylinders. The details of these experiments and the results so far obtained are as follows:—

The Le Chatelier tests for soundness were carried out as specified by the British Standard specification for Portland cement. No appreciable expansion was obtained in any case; yet, some of the concretes were undoubtedly unsound, expanding and cracking badly with time.

Tensile Strength Tests.

These briquettes were of the type specified by the British Standard specification, and required about 26 per cent. of water to obtain a suitable consistency for the neat cement, and 9 per cent. of water for cement and sand mixture (1 part cement, 3 parts Leighton Buzzard sand). They were made and stored as required by the British Standard specification. It was found that the strength begins to diminish only when the addition of gypsum has reached a total of 5-6 per cent., corresponding with 4½-5 per cent. of SO_3. There appears to be a slight increase in strength up to about 4 per cent. added gypsum (corresponding with just over 4 per cent. SO_3).

Compression Tests in Ordinary and Reinforced Concrete.

Blocks were made of cements numbered 1 to 5, 7, 9, and 11. Eight cubes of concrete were cast with each of these cements, giving a total of 64 cubes. The concrete consisted of 1 part cement, 2 parts sand (from Cannock Chase), 4 parts quartzite (from Nuneaton), and was cast into 4-in. cubes and 4½-in. dia. cylinders. Half of these cubes were stored in air in a dry room, and the other half in water. At the end of 11 months the blocks of the first set were broken. The results are given in the following table:—

Cement Sample No.	Compressive Strength.		Remarks.
	Stored in Air.	Stored in Water.	
	Ton per sq. in.	Ton per sq. in.	
1	1.14	1.89	
2	1.04	1.73	
3	1.23	1.60	
4	1.06	1.60	
5	1.15	1.54	
7	0.99	1.80	
9	0.74	1.44	Shows distinct cracks.
11	0.71	0.297	Badly split and cracked.

The specimens from samples 9 and 11 were cracked at the end of 1 month. At the age of 11 months no appreciable increase in the disintegration was apparent over that found at 1 month. The blocks made from sample 11 were very badly cracked and broken, whilst those made from sample 9 had only cracks just appearing. These again were visible at 1 month, and did not appear to have increased on further ageing. Decrease in compressive strength takes place when 6-7 per cent. of gypsum is added (5-5½ per cent. SO_3).

Eight cylinders of each of the mixtures used for the cubes were also cast and were stored under the same conditions as the compression cubes. Forty-eight of these are still unbroken, 24 of which are stored in water and 24 in air. Two pieces of steel were embedded in each cylinder. One was brightly polished and the other one was rusted. After an interval of 11 months a cylinder of each sample was broken open, and the steel bars were examined. In no case was it possible to say that definite rusting had taken place due to the action of the concrete, or due to water and air getting into the concrete. Slight brownish-yellow skins and occasionally rust-markings were found on some of the bright bars.

Summary and Conclusions.

(i) High percentages of gypsum reduce the strength of cement, cement mortar, and concrete.

(ii) At the end of 1 month concretes with cement containing over 6 per cent. SO_3 were cracked, and with 6½ per cent. SO_3 were badly cracked.

(iii) No obvious disintegration during a period of 11 months was observable on any samples of cement or concrete with a cement having a lower percentage of SO_3 than 6 per cent.

(iv) The Le Chatelier test for soundness fails to detect probable unsoundness due to high gypsum-content.

(v) In none of the samples used was it possible to detect any effect on steel, either bright or rusted, which could be directly attributed to the gypsum content.

The conclusion as to soundness is clearly of the greatest importance, and when analyses of the cements are not directly made, or supplied by the makers, it is suggested that blocks should be kept under observation for at least 1 month. If these do not show signs of cracking after that period, there will probably be little fear of cracks developing later.

* Abstract of paper read by Professor F. G. Lea and Dr. R. E. Stradling before the Institution of Civil Engineers.

THE COATING OF METALS.—When metal is applied to a thoroughly clean surface by the Schoop process, the metal coating is extremely tenacious, says the *Revue de Métallurgie*. The strength of this adhesion was thoroughly proved during the war, when metallic coatings were applied to shells and other projectiles; after firing, the coating was found still adhering perfectly to the fragments of shell. Further experiments have proved that the applied metal will resist vibration, bending and even twisting without flaking off. Since the strength of adhesion on a given surface is not the same for all deposited metals, it cannot be assumed that adhesion results entirely from the interlocking of the projected particles with the minute inequalities of the surface. Of the metals most commonly used for deposition the following is their order in strength of adhesion on an iron surface:—Zinc, aluminium, lead, tin, copper and bronze. Aluminium and zinc adhere strongly to copper, as does also tin.—*Engineering*.

CANADIAN BENTONITES.

CHEMICAL AND PHYSICAL CHARACTERS.

A DETAILED account of the occurrence, properties and uses of the valuable new clay "bentonite" was given in the *Chemical Trade Journal and Chemical Engineer* for December 15, 1922 (page 731). The chemical and physical characteristics of the substance have been studied by the Mines Branch of the Canadian Department of Mines, and in the report of the Department for 1921 the results of these investigations carried out by E. A. Thompson and A. Sadler are given:—

The variety of clay known as bentonite occurs at several localities in western Canada. It differs in several respects from ordinary clay, and possesses properties which it is believed will make it of considerable economic importance. When freshly exposed it varies from a light yellow to light olive green, with waxy lustre. The clay is exceedingly fine-grained, and has a soapy feeling when wet. It swells and forms a jelly-like mass in an excess of water.

Its chief use, hitherto, has been as a filler in paper manufacture, but it has been suggested that it might be employed for any of the following purposes: (1) soap making, in which process it can actually replace a portion of the soap substance; (2) as a filler in rubber, textiles, leather, phonograph records, cordage, pressed and moulded insulations; (3) as an ingredient in gypsum and lime plasters; (4) in ceramics; (5) for replacing in part, the bonding clay in abrasive wheels, graphite crucibles, chemical and electrical porcelain; (6) as an adhesive paste; (7) for dehydrating crude petroleum; (8) as a water softener, and base for massage creams; (9) in printer's ink; (10) as a substitute for fuller's earth.

Analyses of Canadian Bentonites.

Eight air-dried samples from five widely-separated localities have been analysed by Mr. A. Sadler as follows:—

—	British Columbia Top.	British Columbia Middle.	British Columbia Bottom.	Princeton.	Camrose.	Rosedale.	Wyoming (I.)	Wilkinite.
H_2O at 105° C.	3.92	6.64	6.09	7.71	5.94	8.10	5.80	11.91
H_2O over 105° C.	4.28	4.92	4.73	3.24	3.70	4.28	3.67	3.24
SiO_2	69.70	67.04	69.60	68.60	60.78	54.88	66.90	53.90
FeO	0.23	0.23	0.22	0.32	0.43	0.22	0.12	0.18
Fe_2O_3	2.88	2.79	1.79	2.00	3.67	4.10	2.80	3.21
Al_2O_3	14.00	13.46	11.84	12.10	17.08	19.92	15.26	18.00
CaO	1.56	1.78	2.28	1.84	2.84	2.22	0.46	1.00
MgO	1.81	1.93	1.75	1.84	2.16	2.83	2.26	3.61
TiO_2	0.23	0.25	0.20	0.14	0.22	0.25	0.11	0.65
P_2O_5	0.014	0.09	0.09	0.17	0.033	0.09	0.04	0.10
Na_2	1.09	0.53	0.48	0.50	1.54	1.75	2.12	2.72
K_2O	0.29	0.22	0.14	0.23	0.46	0.26	0.42	0.21
SO_3	none	none	none	0.61	0.005	0.16	0.08	0.19
S	0.016	0.008	none	none	0.04	none	0.018	none
CO_2	0.04	0.02	0.73	0.17	0.11	0.37	0.05	0.21
Cl	trace	trace	trace	trace	trace	trace	trace	trace
C	0.09	0.10	0.07	0.08	0.13	0.07	0.03	0.53
N	—	—	—	—	—	—	—	none
	100.150	100.008	100.01	99.55	100.138	99.50	100.138	99.66

The foregoing analyses were undertaken with four objectives in view:—(*a*) To ascertain if any definite chemical relationship existed between the several samples; (*b*) to calculate, if possible, a definite (mineralogical) formula for bentonite; (*c*) to discover its origin; (*d*) to have an accurate and complete record of its composition.

Comments on the Analytical Results.

Comments on the results are:—(*a*) The silica content in these clays varies widely from 53.90 per cent in the wilkinite to 69.70 per cent. in the British Columbia (top) sample. The alumina varies from 11.84 per cent. in No. 3 to 19.92 per cent. in No. 6. These variations of the alumina and silica do not indicate a very definite relationship between the materials of the different deposits. Apart from these the amounts of the other constituents agree quite closely. It was noticed that a high silica content is attended by a low alumina. The converse is also true. (*b*) The calculation of a formula does not appear to be possible at present. This may be accomplished after a microscopic examination has been made. (*c*) Analysis does not give any definite information as to the probable origin of these clays as it does in the case of kaolin. The probability is that these were derived from highly siliceous rocks, possibly volcanic, which have undergone subsequent alteration. (*d*) These analyses, it is believed, constitute the most complete record of composition of Canadian bentonite at present available.

Analyses of certain American bentonite clays are given in the issue of the *Chemical Trade Journal and Chemical Engineer* referred to above.

Water Absorption, Specific Gravity, and Fusion Points.

One gramme from each of the undermentioned samples was found to absorb the indicated number of grammes of water. Clay and water in contact for 24 hours:—

British Columbia	1.53
Camrose	4.15
Rosedale	4.71
Wyoming	4.93
Wilkinite	4.95

Crude material, ground to 100 mesh, dried at 105° C. for 2 hours. Determination by pyknometer, gave the following results:—

British Columbia (composite)	2.44
Rosedale	2.72
Camrose	2.73
Wyoming	2.77
Wilkinite	2.78

The fusion points were determined as follows:—

	Cone No.	Temp.
British Columbia	15	1430° C.
Rosedale	14	1410° C.
Camrose	1	1150° C.
Wyoming	11	1350° C.
Wilkinite	10	1330° C.

Effect of Heat on Colloidal Properties.

Determinations were made of the water remaining in the clay after it has been heated to the indicated temperatures for a period of one hour. It was also found that after heating to a certain temperature, which differed in the different samples, that the swelling property was destroyed, and that the other colloidal properties were diminished as the temperature increased. The results obtained are indicated below:

Percentage Amount of Water Remaining in the Clay.

—	Before Heating.	450° C.	500° C.	550° C.	600° C.	700° C.
B.C. Composite	4.64	*4.04	3.94	—	2.53	1.50
Camrose	3.70	—	*3.60	—	2.09	1.14
Rosedale	4.28	—	—	*4.17	—	—
Wyoming	3.67	—	3.49	—	*3.43	0.77

* Swelling property completely destroyed.

The foregoing results show that there is no fixed relation between swelling properties and the quantity of combined water present. In the B.C. sample, swelling was destroyed at 450° C., and in the Wyoming sample at 600° C., and yet they both retained the greater quantity of their combined water. It was also found that after heating from 400° C. to 600° C., there remained only a very small quantity in suspension after standing in water for 24 hours. Heating to 700° C. destroyed the colloidal property altogether. Even at 700° C. combined water still remained in the clay.

CONCRETE IN CHEMICAL ENGINEERING.*

METHODS OF INCREASING IMPERVIOUSNESS TO CHEMICALS.

THE use of concrete in chemical-manufacturing plants may be divided into the following general headings: buildings proper, and tanks, containers, etc.

Concrete in Building Design.

The methods of design of ordinary concrete buildings are matters of more or less common knowledge to structural engineers. There are, however, some qualities which seem to pertain with especial importance to buildings used for chemical-manufacturing purposes. Among these may be mentioned fireproofness, inherent sanitary qualities, and resistance to wear or attack from chemicals. Floors should be able to resist wear from foot and truck traffic, be easy to clean, and not be disintegrated by chemicals which may come into contact with them. A well-made and cured concrete floor will leave little to be desired in its ability to resist wear and fire and the ease with which it may be cleaned, but the question of the action of chemicals on it may need separate attention. Reinforced concrete girder spans of over 125ft. have been used in buildings. Floor loads as high as 2,000lb. per sq. ft. have been carried by concrete floors. Exhaustive fire tests on building columns conducted at the Underwriter's Laboratories, Chicago, showed that the columns having the highest rating consist of reinforced concrete columns with 2in. covering over the steel reinforcement and structural steel columns with 4in. covering of concrete over the steel. It is also worthy of note that the aggregate used in making the concrete has a decided effect on its fire-resistive ability. Thus, quartz aggregate has a tendency to spall off and expose fresh concrete or the reinforcement to the heat. Limestone or calcareous aggregate, on the other hand, calcines on the surface exposed to the heat, but the process of calcination is retarded or wholly inhibited by the protection to the underlying concrete afforded by the surface calcination. This protective coating has a counterpart in the case of many chemicals in contact with concrete. Certain acids form chemical compounds with the cement, which act as protective coatings and inhibit or greatly decrease further chemical action.

Chemicals that have been Stored in Concrete Tanks.

While no hard and fast law can be stated as to the chemicals which do not injure well-made concrete, it is fairly well established that the chlorides may be regarded as harmless, and some of the silicates as beneficial. A partial list of substances for which concrete tanks have been used is given in the following list:—

MATERIAL CONTAINED.	TREATMENT OF CONTAINER.
Crude oil, Light oil, Petroleum oil, Road oil	No treatment in many cases. Sodium silicate, neat cement wash, cement mortar coat, smudging oil, oil-proofing enamel, special varnish and proprietary surface coatings, gunite lining
Menhaden oil, Linseed oil, Rosin oil	No treatment
Sulphite liquor and cider vinegar	Surface coating of 1 part gilsonite, 2.5 parts turpentine, and 5 parts neutral petroleum oil by weight
Benzine	Surface coating of gelatin and glycerine applied hot
Salt brine	No treatment
Molasses	Mostly untreated. Some given inside coating of coal-tar pitch, Portland cement, and kerosene.
Coconut oil	Bakelite varnish
Glycerine	Bakelite varnish
Cottonseed oil	No treatment.
Soya-bean oil, Fish oil, Peanut oil	Sodium silicate
Ammonia (solution)	Coated with tar on inside
Bisulphite of lime	No treatment
Chloride of lime	No treatment if in dry state
Calcium chloride	No treatment
Electrolyte	Depends on liquid. Asphalt coating given to tanks used in electrolytic refining of lead and zinc
Hydrochloric acid	Acid-proof lining
Silicate of soda	No treatment
Sulphuric acid	Fire-brick or acid-proof lining, vitrified tile laid in litharge and glycerine
Wood pulp, Stock chests, Zinc chloride	No treatment
Hemlock liquors, Leaching-bark solution, Tanning liquors, Quebracho extract	Brush-coat neat cement or plastered coat cement mortar
Buttermilk	Coats of neat cement grout
Log boiling	Coated with cement mortar
Slime settling	No treatment
Gas purifying boxes	No special treatment
Caustic soda	No treatment
Corn syrup, Glucose	Acid-proof lining

* Abstract of paper by A. C. Irwin and F. W. Ashton, of the Portland Cement Association, Chicago, presented before the American Chemical Society, in April. From complete paper in *Industrial and Engineering Chemistry*, June, 1923.

The Two Classes of Protective Methods.

Methods of protecting concrete against chemical action may be divided into two general classes—viz., admixtures to the concrete through the cement or water or both; and surface coatings—either as a coating only or as a combined coating and surface-void filler. The question of the value of integral waterproofing compounds in concrete is a very persistent one. The number of these compounds is already so great as to bewilder the ordinary practising architect or engineer in trying to decide which to use. The arguments advanced to explain the beneficial effect of these compounds seem reasonable, but the practical experience had with them is not wholly convincing. Tests are needed—conclusive tests so conducted that each factor influencing the result is carefully segregated so that a proper weight may be assigned to each before accepting the theories of and successful field experience with integral waterproofing compounds. Imperviousness to the passage of ordinary liquids can be obtained by proper attention to the manufacture of concrete. The admixtures so far developed and used may be divided into two general classes—viz., powders, such as hydrated lime, clays, silicates, feldspars, etc., usually mixed with the dry cement; and liquids and pastes, such as insoluble stearate of lime, sodium and potassium oleate in the form of soluble soap, aluminium stearate, calcium chloride, and oil compounds. These are usually added to the mixing water.

Use of Powder as Void Fillers.

Most of the powders are inert, and are supposed to act as void fillers, thus increasing the imperviousness of the concrete. If, however, the admixture is merely an inert material, it is reasonable to suppose that by replacing an equal quantity of cement with inert material the strength of the product is reduced. Where a combined mechanical and chemical action is to be resisted, as when the chemical permeates the concrete and crystallises into larger volume, any decrease in strength is undesirable. Inert material cannot be held in the pores except through the confining action of the hardened cement, and at the surface at least the finely powdered inerts may contribute to weakness where strength is needed to resist mechanical action. The addition of cement instead of these inerts, or, better still, attention to grading of aggregates throughout the mass, thorough mixing, and the use of just enough water to permit thorough compacting in the forms will result in dense concrete of great strength, and at the same time afford a suitable bonding surface for protective coatings if these are required by the nature of the contained chemical. While not a rule of universal and unvarying accuracy, it has been demonstrated that, in general, the properties of concrete, such as imperviousness, wear resistance, resistance to acids and alkalies, etc., increase or decrease with the strength of the concrete. Integral compounds, if used at all, should be selected with a knowledge of the probable chemical reactions involved. With a view to assisting those who may bear the responsibility of deciding just what, if any, admixture to use, a brief outline of the principal ingredients and the action of some of them is presented here.

Quicklime was formerly used with concrete as a densifier, but has been discarded. The use of patented compounds, such as insoluble stearates and resinates, was followed by hydrated lime. Most of the secrets and patented powders are sold on the basis of their "water-repellent" quality. This property is obtained by adding to the powder some metallic stearate, such as lime soap, which is supposed to act as a distributor of the water repellent and as a void filler. Many proprietary compounds are composed mainly of finely ground sand or clay, with or without the addition of hydrated lime or insoluble soaps. Some proprietary cements are mixtures of Portland cement and stearates of lime, or soda and potash with sand and other materials, treated to produce a water-repellent cement. Again, some waterproof cements are made by mixing about 5 per cent.

(by weight) of a lime-oil compound in clinker form, with Portland cement clinker. Fish oil, boiled with hydrochloric acid and mixed with burnt lime while slaking, is also used. The resulting product is a paste which hardens as clinker. Another compound in the form of mortar consists of 1 part by weight of copal gum, 1 part hydrated lime and fine clay, and 1 part Portland cement. The lime-oil cement compounds depend for their impervious tendencies upon the formation of insoluble stearates of lime in the mass and surface of the concrete which act as barricades, and on hydrated lime as an inert void filler. The stearates of soda and potash (ordinary soap) are readily soluble in water, but when in solution in the presence of cement, less soluble lime soaps are formed and precipitated. When used as a surface coating, it is doubtful whether sufficient lime soap is formed and precipitated to act as a protective coating before the soluble soaps are dissolved and washed off. Experience indicates that, in general, surface coatings of soap solutions do not produce lasting results.

Liquids and Pastes as Fillers.

The liquids are mainly composed of metallic salts, such as chloride of lime; they also consist of oil emulsions and soap solutions, and solutions of paraffin in benzine or benzene. The paraffin solutions are applied to masonry surfaces. The waterproofing properties of these liquids depend upon the formation of gelatinous coatings around the smallest particles of the constituents of the masonry. Of course, this would tend to decrease the strength of the concrete, and often does. There is also a coal-tar product used as an integral waterproofing, from which the volatile oils have been almost entirely removed, and the remaining materials tend to bind together the particles of cement and fill the voids in the concrete. Some other compounds are composed of fish oil and water glass (sodium silicate). The fish oil, which is semi-drying, is slowly saponified by the lime of the cement, and the water glass forms a lime silicate, both actions, however, being incomplete, due to the insufficiency of lime present in the cement for such action.

Most pastes are soluble mixtures of secret ingredients which depend for their waterproofing qualities upon precipitation of insoluble materials in the voids of the concrete. Sometimes pastes are made by mixing a powder, such as alum, to the cement, and a soap solution to the tempering water. In making the concrete this paste is added, and the two constituents combine to form a stearate of aluminium, which is a stable, water-insoluble, void-filling compound. Before specifying integral pastes or any integral compounds, it is advisable first to investigate the results accomplished on previous work.

Use of Surface Coatings.

Concrete tanks and containers for liquid chemicals that will attack well-made concrete can be protected with greater certainty of success by the use of impregnative and surface coatings or by membranes than by the use of integral compounds designed to change the action of the liquid on the concrete. The absorptive property of concrete, held in common with practically all non-rusting materials used for the construction of tanks, renders it well adapted to forming a bond with surface coatings. Some of these coatings have already been mentioned, but there are scores of patented and secret compounds of paraffin, tar, elaterite, gilsonite and asphalts, mixtures of alkalies with soap and alum, paints containing suet, asphalts dissolved in naphtha or benzine or mixed with oil and other hydrocarbons, oil-tar pitch, graphite, and several cold-water paints which have Portland cement as an ingredient.

There are so-called, but not true, enamels, consisting of linseed oil and rosin, solutions of Bakelite, etc. There are the iron oxide coatings consisting of pulverised iron mixed with an active oxidising agent such as sal-ammoniac. The silicates and fluosilicates are used both as integral compounds and as surface coatings or "hardeners." Combinations of Portland cement with stearates, calcium chloride, and hydrated lime, combinations of oils partially "rubberised" and dissolved in a mixture of volatile hydrocarbons and turpentine distillates are all used. Lime has been used with cement both as quicklime and in its hydrated condition. At present hydrated lime is used exclusively, either alone or in combination with other materials. Tests indicate a reduction in strength of concrete due to addition of hydrated lime, and the presence of excess lime in concrete used in connection with chemical processes may be highly objectionable. High-magnesium or high-calcium lime is used practically without distinction for waterproofing purposes. Casein mixtures with quicklime, borax, or strong solutions of sodium silicate are also used. Their beneficial effects are supposed to result from insoluble precipitates filling the pores of the concrete. They are used both in surface coatings and integrally. Caustic potash is used with alum as a surface coating, and with various chemicals in secret waterproofing compounds.

The Sylvester process, in which soap and alum are used as a surface coating, consists in the application of a hot solution of about ¾lb. of Castile soap in 1 gal. of water to a dry, clean masonry surface, followed one day later by a coating of ½lb. of common alum dissolved in 4 gal. of lukewarm water. Both coatings are applied with a flat brush and repeated alternately, if necessary. Aluminium soaps are used in many proprietary integral-waterproofing compounds as void fillers and water repellents.

Powdered iron in combination with sulphur, sal-ammoniac, and even with cement is sold under a number of trade names for both integral mixtures and surface coatings. The theory of the beneficial effect of powdered iron is based on the increase in volume occurring on oxidation of the iron, thus filling the pores and forming barricades to the passage of liquids. Resin, or rosin, in combination with various gums is used in a great number of surface-coating compounds. The resin is dissolved in ether, alcohol, or a solvent oil, and used as surface filler. The elastic properties are supposed to be given to the coating by the inclusion of gums in the compound with a suitable solvent such as benzine or benzene. Calcium compounds, as sulphate or carbonate, combined with cement and aluminium compounds, are used in many secret "waterproofers."

Stearin and its derivatives in the form of stearic acid, stearates, and stearin pitch, are included in a multitude of commercially exploited surface-coating and integral compounds. The integral compounds usually employ ammonia or lime. Ammonium stearate, formed by adding stearic acid to excess of dilute ammonia, in the presence of cement forms an insoluble lime or aluminium stearate which is water-repellent. Stearate and asphalt are used as a joint-filling compound, and chemically treated suet as an integral waterproofer for mass concrete. The hydrocarbons and derivatives are so numerous and the method of their use so well known that they need not be discussed here. Specifications for tests and use of various asphaltic and coal-tar coatings have been published by the Bureau of Standards. Asphalts, such as elaterite combined with petroleum oils, linseed oil, gilsonite, and even castor oil, have been given trade names, such as "mineral rubber," and sold as surface coatings.

A simple and yet very effective waterproofing surface coating consists of paraffin dissolved in a suitable volatile solvent. The solvent carries the paraffin into the concrete, where it remains as a complete seal against the passage of moisture. Paraffin is also applied to a concrete surface by melting it and heating the surface to which the paraffin is applied. By skilful use of a blow torch the paraffin may be caused to penetrate some distance into the concrete.

General Conclusions.

In closing the paper the authors emphasise the importance of following implicitly those methods and practices in the manufacture of concrete which have been found in both laboratory and field to result in a product of the highest quality. Integral compounds, surface hardeners, and surface coatings will not in general compensate for careless manipulation of materials. In any investigation, therefore, having for its object the protection of concrete from the action of a chemical which will be in contact with it, the first step should be the preparation of experimental samples of concrete to determine whether or not the particular substance in question will really be detrimental to concrete of the highest quality. If the result of this investigation indicates the need of protection, the most promising procedure will be to study the efficacy of surface coatings for the purpose in hand, rather than the inclusion of compounds in the body of the concrete.

Therapeutics Regulation Bill.—For the regulation of the manufacture, sale, and the importation of therapeutic substances a bill has been introduced by Lord Onslow. The substances to which the bill applies are vaccines, sera, toxins, anti-toxins, antigens, salvarsan and analogous substances, and insulin. The bill provides that only persons licensed shall manufacture these substances, while a similar restriction is placed on importation.

ACTIVATED CARBON.*

GENERAL PROPERTIES, STRUCTURE, AND MANUFACTURE.

ACTIVATED carbon is a comparatively new product. A number of so-called decolourising carbons, which are carbons activated to some extent, have been on the market for several years, but the new and very different product now being produced and used commercially for gas and vapour adsorption was developed during the war, in answer to the demand for a material of great adsorptive capacity for use in gas masks. The discovery of the fundamental factors involved in its production is, without doubt, one of the outstanding scientific achievements of recent years. Gas-mask carbon, however, although more highly active than any carbon produced before its development, does not effectively decolourise and purify many liquids. The fundamental reasons for this, and the essential characteristics of highly activated carbon which will most effectively decolourise and purify various types of liquids, were discovered later, however, by the writer.

One distinction should be clearly made at the outset, to avoid possible confusion. *Active* carbon is regarded as a fairly definite physical entity of well-defined properties. The so-called *activated* carbons of commerce are not pure active carbon, and may vary enormously in porosity or density, strength, hardness, etc., by reason of the associated inactive carbon structure. Yet upon these secondary and incidental properties may depend the commercial usefulness of the carbon for a given industrial purpose. It is now known that the carbon must not only be active, but must also possess special physical and structural characteristics to make it effective for special purposes. There is no one type of activated carbon that can be universally effective for all purposes. Two activated carbons may contain the same percentage of active carbon, but one may be extremely valuable as a commercial vapour adsorbent, while the other, because of its low density, softness, etc., may be practically worthless for this purpose, though very valuable for decolourising sugar solutions.

Chaney's Theory of the Formation of Activated Carbon.

The only theory of the nature and formation of activated carbon which satisfies the known facts is that given by Dr. N. K. Chaney. According to this theory, active carbon exists as a distinctive physical modification, differing from other known inactive forms of carbon by some characteristic peculiarity of molecular structure or arrangement. To this characteristic structure are attributed its special properties —namely, its unique adsorptive power for gases and vapours, and, for certain substances in solution, its unusual chemical activity, and the limited temperature range of its formation. It has been demonstrated experimentally that the elementary carbon formed by the decomposition of carbon-containing compounds may exist in two forms—one of which is active and the other inactive. The temperature of carbon deposition appears to be the controlling factor—the carbon deposited below 500-600° C. being active and that deposited above this temperature range being inactive. Carbon deposited by the catalytic decomposition of carbon monoxide by ferric oxide at 300° C. is highly active. Also carbon deposited by the reaction between carbon tetrachloride and mercury or sodium amalgam at relatively low temperatures is active. On the other hand, the carbon deposited by cracking methane, for example, at high temperatures is inactive.

Applying this theory to the commercial preparation of activated carbon, it will be seen that the low-temperature carbonisation of vegetable materials, such as wood, nut shells, etc., would be expected to give a certain amount of active carbon. Why, then, does not ordinary charcoal exhibit the properties of activated carbon? The answer is that during the ordinary process of carbonisation the active carbon formed adsorbs certain hydrocarbons and stabilises them, so that they are retained under conditions of temperature and pressure which would ordinarily decompose or eliminate them. This has been experimentally shown. The active carbon, being already saturated, cannot, therefore, exhibit any further adsorptive power. The term *primary carbon* has been applied to this complex of stabilised hydrocarbons adsorbed on an active carbon base. Ordinary vegetable chars, low-temperature carbonisation cokes, blacks, and coals belong to the class of primary carbons, and from all these products activated carbons suitable for commercial uses can be prepared. On the other hand, cokes and other forms of carbon that are formed at high temperatures invariably consist largely of the inactive variety of carbon and cannot be activated.

Structure of Activated Carbon.

To be effective as an adsorbent the active carbon must be exposed and accessible. All highly adsorptive activated carbons are therefore either highly dispersed or are traversed by innumerable canals or capillaries, whose chief function is to permit free access to the particles of active carbon. The diameter of the submicroscopic capillaries in a highly activated coconut charcoal has been calculated from vapour-pressure measurements to be of the order of 10^{-6}cm. The surface thus rendered available per cubic centimetre of this carbon has been variously calculated to be from 120 to 1,000 sq. m. When such a carbon is exposed to a high concentration of condensible vapour, a certain amount is adsorbed on the immense surface of active carbon exposed, and a further amount is condensed in the capillaries of varying sizes. However, if such a carbon is exposed to a very low concentration of vapour, a considerable amount will still be adsorbed by the active carbon, but none will be condensed in the larger capillaries. This ability of activated carbon to take up vapours that are present in extremely low concentrations is one of its characteristics which distinguish it from other absorbents that are merely porous, and whose adsorptive capacity under these conditions is very small.

The desideratum for a gas-adsorbing carbon is that it shall have the maximum adsorptive capacity per unit of volume, rather than per unit of weight. This means that the largest *mass* of active carbon must be contained in unit space consistent with maintaining free access or passageway to all the particles in such mass. In other words, the carbon must not be too dense or its permeability is destroyed, and it must not be porous to the extent of needlessly sacrificing adsorbent material. If the density of the carbon falls below a critical minimum value, adsorptive capacity per unit of space begins to be lost. The best gas-adsorbent carbon is relatively dense. Activated coconut charcoal of maximum adsorptive capacity per unit of volume has a block density of approximately 0.66. Carbons that are to be used for industrial gas and vapour adsorption must also be mechanically strong in order to resist the crushing and abrading action to which they are usually subjected. Fortunately, the materials, such as activated coconut charcoal and certain activated synthetic products which have maximum adsorptive capacity per unit volume, are also mechanically strong and eminently suited to resist crushing and abrading action.

Considering now activated carbons for use in adsorbing substances from liquids, we find that again the extent of the available active carbon determines the decolourising or purifying value of the carbon. In the case of gas-adsorbing carbon, capillaries of almost molecular dimensions are desired to open up the active carbon, because the smaller the capillaries and the more numerous they are, the greater the adsorptive capacity per unit volume of carbon; but in the case of adsorbing substances from liquids, in many instances the small capillaries which satisfactorily make available or open the active carbon for gases and vapours do not make it available for adsorbing colloidal materials or larger molecular aggregates. The type of activated carbon that is most effective under these conditions is a highly porous material traversed by pores of relatively large size. Such a carbon has a low apparent density and is more readily crushed than the dense gas-adsorbing type of carbon. Since this type of carbon is generally used in a finely divided form, its relative softness is not an undesirable property. Such a carbon, however, should not powder or "slime," because in this condition it cannot be readily filtered from the liquid. A finely divided "grainy" or fibrous carbon, such as the carbon produced by the Chaney activation process from wood, is not only a most effective adsorbent but an excellent filtering medium.

Proposed Manufacturing Processes.

The raw materials available for the manufacture of activated carbon are, as previously indicated, various vegetable substances or chars prepared from these substances, coals or low-temperature cokes, and many other organic substances, such as oils, gases, etc., which can be decomposed to give carbon. No matter what material is employed,

* Abstracted from paper by Mr. Arthur B. Ray, of the Union Carbide and Carbon Research Laboratories, Inc., of Long Island City, N.Y., U.S.A., in *Chemical and Metallurgical Engineering*, June 4, 1923.

it is essential that the carbon be deposited at temperatures below 600-700° C., and that the adsorption of hydrocarbons by the active carbon be prevented, or that the adsorbed hydrocarbons be eliminated in such a manner as to leave the active carbon base free. The processes by which various types of activated carbon can be made may be classified as follows: (1) Processes depending on the action of inorganic chemical compounds either naturally present or added to prevent the formation of the adsorption complex during carbonisation, or to cause the breaking down and elimination of the adsorbed hydrocarbons during the succeeding calcination. (2) Processes depending on solvents to eliminate the hydrocarbons. (3) Processes depending solely on long-continued calcination to eliminate the hydrocarbons. (4) Processes depending on selective oxidation to break down and remove the adsorbed hydrocarbons and to alter the porosity of the carbon.

By far the greater number of processes for producing decolourising carbons that have been disclosed or patented belong to the first group. The raw materials employed in these processes are practically all of such a character as to give soft, highly porous products which contain some active carbon. The carbons produced, though valuable for decolourising liquids, are practically worthless for adsorbing gases and vapours. In most cases the raw material is admixed or impregnated with various chemicals. The number of compounds that may be used more or less successfully in producing decolourising carbons is large. The following may be mentioned: Alkali hydroxides, carbonates, and sulphates; alkaline earth oxides, carbonates, chlorides, sulphates, phosphates, and acetates; zinc chloride; manganese oxides; and phosphoric and sulphuric acids. Various proportions and mixtures of these chemicals are employed, and to be most effective they must be mixed with the vegetable materials prior to their carbonisation. The final calcination is in general carried out at temperatures around 900° C. The residual chemicals must be removed before the carbon can be used, and in those cases where acid is required the extraction is costly.

Since the formulation of the activation theory previously discussed, suggestions have been made from time to time that the hydrocarbons with which the active carbon base of primary carbons is saturated be removed by suitable solvents. All the various well-known solvents for resins, tars, and pitches have been suggested. The use of selenium oxychloride for this purpose has been patented. Even assuming that all the objectionable hydrocarbons are soluble in the special solvent, the trouble with these schemes is that no provision is made for removing the solvent which is readily adsorbed or for controlling the porosity of the carbon, both of which steps are necessary before the carbon can have any special value as an adsorbent.

It is claimed that certain carbonisation products or primary carbon materials may be partly activated by long-continued heating in a neutral atmosphere at temperatures around 850° C. Our experience and the experience of others indicate that any activation obtained by such treatment is fortuitous, in that it is largely due to the oxidising action of air originally held in the pores of the primary carbons, or which enters the apparatus during the calcination. Activation by heat-treatment alone cannot be successfully accomplished because the hydrocarbons present are cracked at the high temperatures employed and inactive carbon is deposited upon the active carbon base. The resulting product has little or no activity. Active carbon is actually deactivated by a very slight deposition of inactive carbon upon it by the cracking of such a hydrocarbon as methane at 1,000° C.

Principles of the Chaney Process.

Processes in which a selective oxidation is employed to render available active carbon initially present in the material treated are far superior to any other as yet developed for the preparation of highly activated carbons possessing particular structural characteristics. It is only by the use of such processes that it is possible, at the present time, to manufacture in quantity a carbon which meets the requirements of a commercial gas and vapour adsorbent. It was this method of activation that was employed exclusively by the U.S. Chemical Warfare Service during the war. The process was developed under the stress of urgent war-time necessity by Dr. Chaney.

Dr. Chaney's contribution consisted essentially in an apprehension of the following fundamentals: (1) Certain varieties of carbon are inherently inactive, and selective oxidation can be effective in causing activation only when applied to materials sufficiently free from the less easily oxidisable inactive carbon. (2) A material amenable to activation by selective oxidation and free from inactive carbon can be prepared only if the carbon is liberated below certain critical temperature limits. (3) A material containing active carbon is ordinarily useless as an adsorbent until this active carbon is freed from the hydrocarbons saturating it, and maximum adsorbing efficiency can be attained only when the maximum proportion of the active carbon present has been rendered available.

The principles enunciated by Chaney, and the process which he based on them, are the foundation on which has been built the National Carbon Company's output of activated carbon. Despite the limitations imposed by the first principle, it was early demonstrated that the raw materials in which a sufficient amount of active carbon, sufficiently free from inactive carbon, was present or could be produced were more numerous than the materials that theretofore had been regarded as promising sources of gas-adsorbent carbon. It has further been found possible to produce superior decolourising carbons from a variety of raw materials by employing the selective and limited oxidation processes which enable the dispersion or porosity of the activated product to be controlled. In fact, all types of primary carbons may be activated by this general process to give many new and different types of activated carbons suitable for different purposes.

The primary carbons as defined by Chaney include all chars, cokes, and carbon materials formed at low temperatures—below 600-700° C. Vegetable chars, carbon blacks, lamp-blacks, low-temperature cokes, and coals containing a small amount of volatile matter, come under this definition. Some of these materials may be heated to temperatures above 700° C. without becoming seriously contaminated by inactive carbon deposition as a result of "gas-treating." Other materials will become self-gas-treated if heated at a high temperature, and then cannot be activated because selective oxidation will destroy the active carbon rather than the inactive carbon thus deposited.

When a gaseous oxidising agent is employed, such gases as air, carbon dioxide, and steam may be used. The process employing air as the activating agent has the advantage of relatively low-temperature operation—around 350° C.,—but the rise in oxidation potential with temperature is very rapid and the process is extremely difficult to control. As previously explained, a *selective oxidation* of the residual hydrocarbons is desired. The oxidation by air, however, has been shown to be less highly selective; and, consequently, while a considerable amount of carbon is oxidised, the remaining carbon is only moderately activated. While the highest quality active carbon has not been produced by the air activation process, an appreciable percentage of the carbon made by the U.S. Chemical Warfare Service for gas masks during the war was so activated.

Processes employing carbon dioxide or steam have the disadvantage of high-temperature operation—around 900° C.,—but these reagents exercise a selective oxidising effect, and the reaction, being endothermic, is readily controlled. Flue gas containing carbon dioxide has been used to produce some fairly well activated carbon; but, after a very extended investigation, it has been concluded that more highly activated carbon can be produced by steam activation. It appears also that the removal of the hydrocarbons with a minimum of "cracking," and consequent deposition of inactive carbon, can be accomplished only when the concentration of the oxidising agent is high. This means that the steam, for instance, must be introduced in excess, and that the reaction products must be effectively led away. The operating difficulties are further increased by the fact that all primary carbon materials are very poor conductors of heat.

The great advantage of the Chaney process is that by employing proper steam rates for different periods, at selected temperatures, the characteristics of the activated product may be widely varied within limits depending upon the character of the primary carbon employed. This may be strikingly shown by data concerning the relative variations in properties of coconut charcoal activated under one set of conditions for various lengths of time. The data show that the activation process proceeds in two distinct stages—viz., a stage in which the percentage hydrogen content is being rapidly reduced, and a stage in which the percentage hydrogen content is being reduced very little or not at all. Approximately 20 per cent.

of the charcoal is gasified during the first stage. The material removed has an average percentage hydrogen content of 11.6 and is quite evidently hydrocarbons. Until the bulk of these hydrocarbons are removed the material has no appreciable saturation or retentivity value. As the activation proceeds into the second stage, however, the material removed by selective oxidation has an average percentage hydrogen content of 0.78, and must, therefore, comprise a comparatively very large proportion of uncombined carbon and a comparatively small proportion of hydrocarbon. During this stage both the saturation and retentivity increase, the saturation increasing at an approximately constant rate to the limit to which the tests were carried, and the retentivity increasing at a diminishing rate to a maximum when about 60 per cent. of the charcoal has been oxidised.

From these considerations it is obvious that to produce a carbon for use as a gas or vapour adsorbent having maximum adsorptive capacity per unit of volume a dense primary carbon must be used, and the activation process continued only long enough to obtain a maximum of active carbon exposed. If, however, a highly porous carbon is desired for storing gases, or for removing colouring matters and impurities from certain liquids, a highly porous primary carbon may be used and the activation continued only until maximum active carbon is exposed; or a dense primary carbon may be subjected to selective oxidation until it possesses the necessary porosity.

THE BRITISH DYESTUFFS INDUSTRY.

HOUSE OF COMMONS DISCUSSION.

On Wednesday of last week, in the course of the debate on the Board of Trade Estimates, Lieut.-Commander Kenworthy raised the question of the Department's policy in regard to the dyeing and dyestuffs-making industries of this country. The opening up of the subject gave the opportunity to Dr. G. C. Clayton, the member for Widnes, to speak authoritatively as follows:—

It is extremely satisfactory to me that the President of the Board of Trade is so interested in the development of the industries of this country. If in the past the Board of Trade had taken the same interest in the manufacture of dyes we should never have lost that industry in this country. We started it here, and we had the raw materials and the knowledge, but at that time there were a great many restrictions put upon the industry by the then Board of Trade, and it drifted away and went to Germany, where they gained the advantages that we could not obtain in this country.

The Industry a School for Chemists.

We have all the raw materials for the dye industry. Prior to the war a great deal of that raw material was sent to Germany, worked up there with their labour and consuming their raw materials, coal, etc., and it was returned to this country in the form of dyes and used by us. There is no reason why those dyes cannot be made here. I am pleased to say, from what I know of the industry, that enormous progress has already been made. Great satisfaction has been given to the dye users. There may have been some who had some difficulties in obtaining the dyes they wanted, but generally there has been great satisfaction. They agree that very great progress has been made, and I feel sure that under the help and guidance of the present Board of Trade we shall have established in this country a dye industry that can hold its own with any other dye makers. Apart from the fact that we have all the raw materials to make the dyes in this country, the dye industry requires a very great deal of labour, not only in actually making the dyes, but in preparing the raw materials for those dyes. I want that labour to be found in this country, and not in Germany. We have also to consider the safety of the textile trade in this country. We must have an adequate supply of dyes on which we can rely as being made in this country. There are times, such as the present time on the Ruhr, when it is impossible to get dyes. Other occasions might easily occur when it will be impossible to get foreign dyes, and we must maintain our textile trade. I feel that it is very important for that reason also that we should have a dye industry here.

Further than that, the dye industry is a most valuable school for chemists. A very large number of chemists are required both in the manufacture of the intermediates and of the dyes, and as a school for chemists it is of great value. These chemists are used in every other industry, and we could draw on the dye industry for these men when required. If we have no such school we fall behind in very many of our industries. I maintain that the chief objections to this subsidy to the dye industry come from the merchants who supply the German dyes. I do not believe that the objections really emanate from the users, but from these traders in foreign dyes. I think our British interests are vastly more important than the interests of these dealers in German dyes.

The Position of the Merchant.

Mr. J. Hope Simpson: The trouble under which the dyeing industry is now labouring has been represented in this House on more occasions than one. The effect on the merchants is probably the greatest of all. The chief opposition probably comes from that quarter. The hon. member for Widnes (Dr. Clayton) seemed to suggest that it did not matter very much what happened to the dye merchant, but, as a fact, the dye merchant plays a very important part in the organisation of the dyeing industry. He deals with the small men, and he has opportunities for scientific investigation, and he also has experience on a far more important scale than any of these small men can have, and, as a fact, the smaller dye users resort to the larger merchants and rely on their skill and experience for advice with regard to the dyes they shall use. Again, the merchant has machinery for importing and for dealing with large quantities of dye, whereas the small man would find great difficulty in obtaining small amounts of dye at all if it were not for the merchant. The merchant, under the present administration, is being systematically squeezed out of the trade. The greatest evil of all is the compulsion on the merchant to reveal the name of his customer. I have no doubt there is some good reason for that which the right hon. gentleman will explain. The merchant himself feels it very seriously, because that is one of the trade secrets which he naturally wishes to keep to himself. On the Committee there are members whom he regards as trade rivals, and to them least of all he would desire to expose the list of his customers.

Mr. Simpson then gave, at considerable length, several instances of dissatisfaction in the colour-using industries, and amongst merchants.

The Reply of the Government.

Sir P. Lloyd-Greame, the President of the Board of Trade, replying to the criticism of the Government's dyestuffs policy, said: It has been said that it is unfair for the merchants to have to give particulars. But it is most necessary that merchants should be made to give these particulars. After all, what is this Licensing Committee? Remember that on it the makers of the dyes are in the minority and the users in the majority. They want to be satisfied about the price; they want to be satisfied that the dye is necessary because the applicant who is going to use it cannot get a suitable British substitute. It is necessary to get some further particulars from the merchant, as otherwise he may propose to bring in tons of German dyes and sell them wholesale in this country. The merchant is required to prove two things. One is the price which will be charged to the consumer; the price to the merchant may be one thing and the price at which the merchant passes the article on to the buyer may be a totally different thing. Therefore this Licensing Committee requires to be satisfied, and quite rightly, as to the price to be charged to the man who is going to use the dye. They also want to know from the man who uses it and who has to sell his product what is the suitability of the dye for the purposes he requires it for. It is utterly unreasonable we should be asked to deprive the user or the maker of these very necessary safeguards.

Foreign Manufacture of Textiles Increasing.

I want to come to the broad question of policy, because on that so much depends. I have no hesitation in saying that the value of the dye industry to the textile industry of this country is greater to-day than it ever was before. Just look at what has happened in the course of the last six months. We have had the occupation of the Ruhr, which has lessened the facilities for exports of dyes from the Con-

tinent, and it has been of the greatest advantage to have a dye industry in this country. The textile trade, whether in Lancashire or Yorkshire, would have been in a very anxious position in the last six months if it had had to rely entirely on dyes coming from the Continent. Let the hon. member note another fact. The position of the textile trade to-day is wholly different from what it was before the war. Before the war the textile trade enjoyed a predominance which was unique. Look at the exports of one industry in this country—an industry which, whether in times of trade boom or slump, has gone on steadily producing textile machinery, and that textile machinery has been going out of this country to be erected in competing markets. The trade of this industry has gone on increasing when every other trade has been bad. The increase has been constant, and the manufacturers of textile machinery have been unable to keep up with the demand. The hon. member will not suggest that the competition of the number of mills growing up all over the world—a number which is steadily increasing—is not an increasingly dangerous position which Lancashire has to face. It would be unwise to leave Lancashire at the mercy of a possible combination of foreign dye-makers and foreign mill-owners..

Finally, there is the question of price. The hon. member quoted prices for this and for that, but he quite forgot to tell the House what has been the common experience in case after case. It is this: that it was only when we made the dyes in this country that the German prices came down. If you give up making dyes here, do you suppose the German dyes will stay at their present low level? Of course, they will not. As soon as the Germans again get the market, up will go their prices, and then what have you got for your own industry? You have no guarantee of any dyes at all. You have no guarantee that you will get them at reasonable prices. I do not think that that is likely to appeal to the common sense of the textile world.

ZINC AND LEAD COMPOUNDS IN AMERICA.

INCREASE IN PRODUCTION IN 1922.

FROM figures compiled by the Geological Survey, it is evident that substantial increases in production were made in the cases of lead and zinc pigments in 1922. The figures as issued give totals marketed rather than produced, but are relatively true in either case as an index of larger supplies.

Notable increases were made in the sales of all zinc pigments and salts except zinc chloride, but there was a falling off in the average price per ton. The largest output of zinc oxide made in the history of the industry was recorded, the gain amounting to 73 per cent. over the output in 1921. The amounts marketed were as follows:

—	1921.		1922.	
	Short Tons.	Value Per Ton.	Short Tons.	Value Per Ton.
		Dols.		Dols.
Sublimed lead*				
White	11,568	122·61	13,765	132·94
Blue	463	126·55	972	132·95
Red lead	21,814	156·36	30,509	167·30
Orange mineral	379	240·59	370	224·38
Litharge	41,953	136·84	58,261	152·63
White lead:				
Dry	26,695	140·47	41,598	139·07
In oil	143,634	192·94	153,393	193·80
Zinc oxide	74,329	151·11	128,465	140·07
Leaded zinc oxide	16,103	129·93	19,613	114·80

Zinc chloride	59,457	59·75	41,627	48·27
Zinc sulphate	3,295	57·47	5,078	49·53

* Includes basic sulphate lead.

OUR BOOKSHELF.

American Petroleum Refining. By H. S. Bell, C.E. London: Messrs. Constable and Co.; price, 24s. net.

A volume definitely designed and compiled for owner, manager, and engineer, so that it is essentially industrial and practical in character. Although secret or semi-secret plant and processes cannot be described in text books of this kind, there is much in this volume which is not generally known. Passing the opening chapters, dealing in a lucid way with the chemical and the physical sides of petroleum, we arrive at the manufacturing sections which comprise the mass of the work. Very clear diagrams showing modern lay-out lead on to carefully expounded detail concerning refining site and general arrangement of the works. Stills, which play such an important part in this industry, are dealt with at length, and as one would naturally expect, there are various of the latest and best stills fully described under this heading, amongst them being the Trumble System installed at the Martinez refinery of the Shell Company and the Foster Tube Still. Condensers and heat exchangers are other sections which chemical engineers in all branches of industry will undoubtedly study with interest and advantage. The Cracking Process contains more definite information than is usually the case, and with the exception of the use of aluminium chloride it is noteworthy that cracking has developed along mechanical rather than catalytic lines—pressure and temperature being the chief factors. Acid recovery involving modern and very effective plant is discussed and illustrated clearly. A very good book which must attract a large number of readers.

LEGAL INTELLIGENCE.

SUPPLY OF PYRITES DURING THE WAR.

Rio Tinto Company, Ltd. *v.* The Crown.

Judgment was given on Friday, July 20, by Sir Edward Pollock, one of the High Court Official Referees, in the claim by the Rio Tinto Company, Ltd., against the Crown for some £900,000. in respect of an arrangement for the supply of cupreous pyrites during the war. It was alleged that the Government in consideration of being supplied with pyrites for the Allies at pre-war rates agreed to facilitate the supply of coal to the Rio Tinto Company, which they failed to do, and the company claimed £188,811. to cover the extra expense to which they had been put in procuring coal. They also claimed £266,700. for loss of copper production owing to the lack of fuel, and £500,000. for the loss of prospective American business. The case was originally heard by Mr. Justice Avory, who gave judgment on April 11, 1922, holding that the suppliants were entitled to a reasonable price for all pyrites delivered after January 1, 1918, and in regard to that matter his Lordship referred the question of the amount due, to the Official Referee.

Sir Edward Pollock, after a lengthy hearing, found that 25s. a ton for pyrites in 1918 was a reasonable price, and to that amount, he said, the suppliants were entitled. The quantity of pyrites in question was, he said, 146,000 tons, to which had to be added £37,652. for extra freight, making the amount due to the Rio Tinto Company on their pyrites claim £220,152.

The Official Referee at the request of Sir Edward Pollock, K.C., appearing for the Crown, did not enter judgment for the suppliants, but left the matter open to be mentioned at a later date.

PUBLICATIONS RECEIVED.

A Treatise on Chemistry.—By Sir H. E. Roscoe and C. Schorlemmer. Vol. II., the Metals, Part I. and Part II. New (sixth) edition, completely revised, by B. Monat Jones and others. London: Macmillan and Co., Ltd.; price, 50s. net.

Annuaire Officiel des Adresses Telegraphiques, the French equivalent of the British "Sells'."—Sole agents in Great Britain and Ireland, Business Directories, Ltd., London, E.C. 4. Price 25s. net.

Czechoslovakia.—Department of Overseas Trade report, dated March, 1923; by Mr. S. P. Elliott, of Prague. Price 1s. 6d. net.

"Proctor's Useful Tables."—Messrs. Edward le Bas and Co. have just published their (1923) booklet of useful tables, which contains a large mass of figures and data of interest to engineers, chemists, and works-managers, in compact and attractive form.

CATALOGUES.

Prospectus.—Issued by the Technical College, Bradford. Diploma and special day courses for the session 1923-24.

Illustration Sheet No. 5569.—Received from Messrs. Manlove, Alliott and Co., Ltd., dealing with various forms of plant supplied by them to the chemical industry.

ITEMS OF INTEREST.

Permitted Explosives in Mines.—A Government order permits the use of the explosive, "Penrhyn Powder," in coal mines.

Aluminium Coins for Germany.—The Reichsrat has adopted the proposal to issue shortly aluminium coins in one denomination only—viz., 1,000 marks, to a total of 240 milliard marks.

Cheaper Benzol.—The National Benzol Company announce a reduction in the price of National Benzol mixture to 1s. 8½d. per gallon, which brings it into line with the present price of petrol.

Obituary.—We regret to announce the death of Mr. William Smith, which took place on Saturday last (July 21) in his 54th year. Mr Smith was for 20 years laboratory steward of the Institute of Chemistry.

Ozokerite Output in Poland.—Production in ozokerite, or mineral wax, in Poland during 1922 amounted to 430 metric tons, of which more than 400 tons was exported, chiefly to Germany, Austria, and Czechoslovakia.

Coconut Factories in Jamaica.—Plans are under way for the formation of a company to erect and operate a number of factories in Jamaica for the production of desiccated coconut, and also to prepare by-products of coconut for the market.

Chemical Society's Library.—Owing to the work of redecorating the rooms of the Society, the Library will be closed during the entire month of August, and in accordance with the usual practice will close at 5 p.m. daily from September 1 to 17.

Imperial College Research Fellowships.—The following awards tenable at the Imperial College during the year 1923-24 are announced:—Mr. F. R. Weston to the Gas, Light, and Coke Company's Research Fellowship, value £175, with allowances, and Mr. H. W. Buston to a Beit Fellowship, value £250.

New Oil Refining Mill at Greenock.—The construction of the new mill of the British Oil and Cake Mills Limited at the James Watt Dock, Greenock, is almost completed, and work will be started shortly. The building occupies 3¾ acres, but the firm have an option to enable large extensions to be carried out if found necessary.

Business Notice.—Messrs. Mantz and Reid, Ltd., state that they have amalgamated the businesses carried on respectively at 1, Leadenhall Street, and 18, Cullum Street, and the combined business will be carried on at:—1, Leadenhall Street, London, E.C. 3. Telephone number: Avenue 8458; and telegraphic address: Imreidex, Stock, London.

National Metal and Chemical Bank.—In the Chancery Division on Wednesday, July 25, Mr. Justice Russell had before him the action of the Tavoy Concessions against the National Metal and Chemical Bank, Ltd., on a summons to vary the certificate of the Master in Chambers, who found that there was a sum of over £27,000. due from the Bank to the plaintiffs. Mr. C. A. Bennett, K.C., stated that the parties had come to terms, and by consent the certificate would be varied by finding that there was £21,628. due to the plaintiffs, and there would be judgment for that amount and the taxed costs. His lordship entered judgment accordingly.

Tariff Notes.—The following articles are added to the list of goods which are imported into South Africa duty-free when produced or manufactured in the United Kingdom or reciprocating British Possessions, and which are dutiable at 3 per cent. *ad valorem* when produced or manufactured in other countries:—Oxalic acid; ammonium oxalate; fuller's earth; red and white lead; lithopone, dry; manganese resinate; naphthalene; nickel sulphate; certain metallic oxides; perchloride of iron, potassium and sodium metabisulphite; gums, shellac and resin size; saltpetre. The Governor-General is empowered to allow under certain conditions a rebate of the Customs duties that would otherwise be payable on the articles enumerated hereunder, on first importation, or when taken out of bond—viz., salt; turpentine, vegetable or mineral; eucalyptus, pine and other oils; soya bean, citronella, and mirbane oils; waxes, linseed oil, raw. The importation into South Africa of carbide of calcium which, when treated with water, yields less than 250 litres of gas from one kilogramme, is prohibited.

The Price of Insulin.—The Minister of Health stated on Wednesday that the prices of insulin had been reduced very materially, and he had good hopes they would be still further reduced.

British Coal Output.—The coal output for the week ended July 14 was 5,041,900 tons, compared with 5,305,800 tons in the previous week, and 4,626,700 tons in the corresponding week last year.

Pyrites Agreement Signed.—The agreement, referred to in last week's issue, between the principal pyrites producers, with a view to developing the consumption of pyrites, has now been signed.

Egyptian Soda Exports.—Exports of caustic soda from Egypt amounted to 1,428 metric tons in 1922 compared with 1,224 tons in 1921, 278 tons in 1920, and 960 tons in 1913. Most of the exportation was taken by Greece and Palestine.

Radium Ore Mines.—The Radium Ore Mines, Ltd., is about to expend £50,000. on augmenting the plant and equipment at its mine, formerly the Tolgarrick Pitchblende Mine, and in further opening up their properties in Cornwall.

Literary Intelligence.—Messrs. Longmans, Green and Co. announce that the new edition of Sir Edward Thorpe's "Dictionary of Applied Chemistry" will extend to seven volumes, a great part of the last volume being devoted to a complete index to the work.

Companies' Winding Up.—The Lord Chancellor has made an order, transferring the jurisdiction of the High Court to wind up companies from Mr. Justice Astbury and Mr. Justice Lawrence to Mr. Justice Eve and Mr. Justice Romer. The order will come into effect on October 12, 1923.

Dispute over Alleged Guarantee.—The appeal of the London City and Midland Bank from the refusal of Mr. Justice Coleridge to enter judgment in the action against James Gibson and others to recover £25,000., with interest, alleged to be due from the defendants (*C.T.J. and C.E.*, May 4, 1923, page 550), was dismissed on Tuesday in the Court of Appeal. It was decided that the case should follow the ordinary course, and be retried.

Ethylene and Acetylene as Anæsthetics.—Recent clinical research has demonstrated the value of both ethylene and acetylene as anæsthetics when mixed with oxygen. Luchhardt and Carter (*J. Amer. Med. Ass.*) May, 1923, state that the opinion is gaining ground that ethylene has some of the advantages of ether without many of its troublesome after-effects. With regard to acetylene, C. J .Gauss and H. Wieland (*Klinische Wochenschrift*, p. 113, 1923) say they have used in 515 major operations a mixture of 40 parts of acetylene and 60 parts of oxygen, with a little oil of pine to mask the odour.—*Chemist and Druggist.*

Salt Manufacture in China.—A Japanese company has obtained permission from the Japanese Government to purchase an area of land in Tingshaho, Dairen, to be used for the establishment of a salt works. Construction work will soon be started, and is expected to be completed in the course of two years. The annual value of the salt output for the first three years is estimated by this company at yen 50,000,000.—The merchants of Fengjun Chihli are organising a salt refining company, under the name of Fu Ho Refined Salt Co., Ltd., with a capital of $100,000. The company is to be located in Tangkiatun, Fengjun, with branches or agencies in other business centres. The temporary office of this company is in Tientsin.

Utilisation of Tin-plate Scrap.—Experiments have been conducted in an electrical furnace by the Department of the Interior at the Bureau of Mines experiment station at Seattle, Wash., states *Engineering*, in which tin-plate scrap was melted with various additional agents. Sodium chloride, iron sulphide and an oxidising slag were tried, but the conclusions reached were that in the electric furnace complete detinning is impossible and any detinning impractical. Melting tests conducted in the cupola showed that the amount of detinning was dependant upon the amount of surface of metallic tin exposed to the oxidising gases, and will be somewhere between the limits of 0 per cent. and 50 per cent. Test bars, prepared by melting pig-iron with various quantities of tin, were subjected to physical tests. The results showed that a tin content of 1 per cent. or less did not seriously affect the properties of grey iron. Cast-iron made from tin-plate scrap was used successfully in making commercial castings of good quality.

University News.—In connection with the resignation of Sir Michael Sadler from the Vice Chancellorship of the University of Leeds an appeal for the establishment of a memorial has been issued. The appeal is signed on behalf of the "Sadler Fund Committee" by the Duke of Devonshire (Chancellor), Mr. E. George Arnold (Pro-Chancellor), Sir Ernest Bain (treasurer of the fund), and others.

American Dyestuffs Industry in 1922.—According to a report published by the U.S. Tariff- Commission, the domestic output of dyestuffs in 1922 by 87 firms was 64,632,187lb., an increase of 66 per cent. over 1921. The increase was largely due to an increase in general business activity, says the report, the textile and other dye-consuming industries becoming more active in the latter half of the year. The average sales price for 1922 was 60 cents per lb. compared with 83 per cent. in 1921.

Fires.—A large building used for the storage of oil, varnish, and waste rubber in Hythe Road, Willesden, and situated near the railway line at Willesden Junction, was partly destroyed by fire on Saturday, July 21. A considerable amount of damage was done before the flames were subdued.—The official report concerning the fire on Friday last at the premises of Messrs. Dussek Brothers and Co., Limited, tar importers, Deptford, states that the part of the premises used as boiling and distilling rooms and stores was severely damaged, and the greater part of the roof was destroyed.

Nitrostarch in Explosives.—The use of nitrostarch in the manufacture of safety explosives is increasing,, and this substance is now important in the explosive industry, state C. A. Taylor and W. H. Rinkenbach, of the Pittsburgh experiment station of the United States Bureau of Mines. Nitrostarch is made by nitrating starches with a mixture of sulphuric acid and nitric acid, and the commercial product is in reality a mixture of compounds of various degrees of nitration, being comparable in this respect with nitro-cellulose.

Swedish Pyrites Deposits.—As the result of vigorous search by the Swedish Geological Research Bureau, a deposit of copper, sulphur, and magnetic pyrites of exceptional richness has been discovered at Malanäs, near Skelleftea. The district is easy of access, and it is estimated that more than half the field contains ore yielding from 5.5 to 7 per cent. of copper and 34 to 38 per cent. of sulphur. These figures compare favourably with those of the Rio Tinto mines. The ore body extends over 2,000 square metres, and should render Sweden quite independent of supplies of Norwegian pyrites.

The Toxicity of Hydrogen Sulphide.—An investigation of the toxicity of hydrogen sulphide has been completed by the Department of the Interior, at the experiment station of the United States Bureau of Mines, Pittsburgh, Pa. According to the *Colliery Guardian* the experiments show that this gas is exceedingly poisonous, as acute poisoning can be caused by breathing air containing as little as seven-hundredths of one per cent. Dangers from the possible presence of this gas in mines and around industrial plants have not been fully appreciated, there being a relatively large number of poisoning cases which might have been avoided if the proper precautions had been taken. The gas is frequently present in small but dangerous quantities in places where sulphur may be present and exposed to chemical action, as in mines, sewers, in sulphuric acid plants, refineries, gas plants and smelters.

Etching Reagents for Alloy Steels.—According to the *Iron Age* (New York), considerable attention was paid recently to the problem of finding an etching reagent by which chromium carbide could be distinguished from vanadium carbide in a positive and satisfactory manner. Only one out of about twenty reagents tried seemed lively to be of much use in this connection. This is a hot solution of potassium permanganate and sodium hydroxide, etching in which for one minute darkens chromium carbide to a strong brown-red or brown colour, or rather, the carbon is eaten out, giving the walls of the cavity thus formed a dark brown-red colour, while vanadium carbide remains uncoloured and apparently unattacked. Another and less positive means of distinction is that obtained by electrolytic etching with a weak current in a dilute aqueous solution of ammonio or sodium hydroxide. The chromium carbide is eaten out, leaving a dark-brown red or brown cavity, while the vanadium carbide is eaten out, apparently at a slower rate, leaving cavities which appear light and not at all darkened.—*Engineering.*

Examination of the Sodium Borates.—According to A. Gawalowski (*Pharm. Monatsh.*, 1922, No. 3, p. 87), sodium metaborate $NaBO_2{\cdot}4H_2O$ dissolved in water and treated with a solution of potassium dichromate gives an intense blue colour. Ordinary borax under similar conditions gives no colour reaction.

Artificial Leather.—Oliver Kemp, in *Export* (New York), states that the breaking and other defects of the old-time artificial leather of canvas have been remedied only after experiments with hundreds of fabrics. The base of substitute leather at last selected is moleskin, a closely woven cotton fabric with a considerable pile. This is given the non-cracking and other qualities of genuine leather by dyeing, passing through a napping machine to give even greater pile, and then giving a series of coatings with a jelly-like mixture of castor oil and a solution of nitrated cotton. The product is then passed through embossing machines. The well-made substitute resists sun heat, rain, snow, and wear from wind-blown sand, as well as the best real leather, and is now in demand for hundreds of purposes.

Water Clarification by Means of Alum.—Messrs. E. J. Theriault and W. Mansfield Clark, of the United States Public Health Service (*Public Health Reports*, February 2, 1923), have carried out a detailed experimental study on the relation of hydrogen ion concentrations to the formation of flock in alum solutions. It has been found that when other possible factors are left out of consideration, optimum conditions for flock formation will be found with a narrow zone of *p*H centred for dilute solutions at *p*H 5.5. The more dilute the water in total salt content and the less the alum added, the narrower becomes the *p*H zone with which optimum flock formation is to be found. Consequently, precise *p*H control should, in favourable cases, permit a great economy in alum dosage.

Distinguishing Test Between Sodium and Potassium.—Solutions of sodium oleate of higher concentration than 5 per cent. form a gel on cooling to normal temperature. Solutions of potassium oleate, on the other hand, state C. W. L. Bourlet and W. Thomas (*Chem. News*, March 29), may be poured from one vessel to another till the concentration reaches about 40 per cent. In the case of the potassium soaps the change of concentration *gradually* increases the viscosity till the mass becomes very viscous, and finally plastic. In the case of sodium soaps, however, the change from solution to gel is sudden; slight variations in concentration or temperature induce enormous variations in viscosity. The addition of phenol or cresol to a potassium-soap solution thickens it; with sodium soap, however, the effect is reversed. To distinguish between a potash and a soda "soft" soap, it is only necessary to prepare a 15 per cent aqueous solution, measure the efflux time at constant temperature from a pipette; then add, say, 4 per cent. of phenol. In the case of a potash soap the efflux time will be increased; in the case of a soda soap decreased.—*Pharmaceutical Journal.*

Separation of the Xylenes.—Contrary to statements in much of the literature on the subject, state H. T. Clarke and E. R. Taylor (*J. Amer. Chem. Soc.*, 1923, 45, 830-835), the three xylenes cannot be obtained in a state of purity from a mixture by distillation only. It is necessary to carry out four operations, fractional distillation, selective sulphonation, fractional crystallisation of the sulphonic acids, and hydrolysis of the acids. *m*-xylene can be obtained in a crude state by simple distillation; to purify it, it may be treated with dilute nitric acid, which only oxidises the *o*- and *p*-xylenes. Technical *m*-xylene may be purified by sulphonating it at 95° C. for four hours, neutralising the product with 40 per cent. sodium hydroxide solution, separating the crystals, and recrystallising the sodium salt of the *o*-xylene sulphonic acid; the salt is then hydrolysed by steam-distillation with dilute sulphuric acid. For the purification of the *p*-xylene, the technical product is sulphonated with sulphuric acid in the cold, the undissolved portion being re-treated in the same way; the undissolved residue contains the *p*-xylene, and is separated and sulphonated at 95° C., and the product slowly mixed with concentrated hydrochloric acid; the *p*-xylene sulphonic acid, which crystallises out, is separated and hydrolysed by steam-distillation with dilute sulphuric acid. The first runnings contain some *m*-xylene, but the fraction distilling above 145° contains pure *p*-xylene, which is again fractionated, and then yields a product boiling between 136.5° and 137° C.—The *Analyst* (May, 1923).

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS IN JUNE

(Concluded from page 76.)

THE following returns, which are taken from the import statistics of the United Kingdom, give the amount and value of chemicals and allied products imported during the month of June, 1923, compared with 1921 and 1922. As from April 1, 1923, the import trade of the Irish Free State is excluded from the Returns.

CARBIDE PRODUCTION IN SOUTH AFRICA.—Judging by the progress made in the domestic manufacture of calcium carbide in South Africa, there is no longer a market in that country for imported material. The present sole manufacturer, Rand Carbide, Ltd., formed in 1922, has an output of 250 tons per month. In 1920, 4,000 tons of carbide was imported. Requirements are 350 tons per month, of which Rand Carbide, Ltd., supplied 313 tons last February. Preparations are now in hand to enlarge the factory.

EXPORTS OF CHEMICALS AND ALLIED PRODUCTS IN JUNE.

(Concluded from page 77.)

THE following returns, which are taken from the export statistics of the United Kingdom, give the amount and value of chemicals and allied products exported during June, 1923, compared with 1921 and 1922. As from April 1, 1923, export trade of the Irish Free State is excluded from the Returns.

GAZETTE NEWS.

MORTGAGES AND CHARGES.

British Cellulose and Chemical Manufacturing Co., Ltd., London, S.W.—Reg. July 6, trust deed dated June 28, 1923 (supplemental to trust deed dated Aug. 4, 1922), securing £1,000,000. (including £500.000. secured by original deed and £200,000. re-issued by this deed) and redemption premium £100,000.

Bute Lime Works Co., Ltd., Pontyclun.—Reg. July 5, £3,000. debs.

Canning Town Glass Works, Ltd.—Reg. July 5, £320,000. 1st debs. and £380,000. 2nd debs. (secured by two trust deeds dated June 28, 1923).

Cross Bone Manure and Lime Co., Ltd., Bridlington.—Reg. July 4, charge, to Barclays Bank, Ltd., securing all moneys due or to become due to the Bank.

Davis and Son, Dyers, London, Ltd., London, W.—Reg. July 4, mort. and a land registry charge, securing £6,000. to Col. W. N. Davis, Salt-hill, Slough.

Devon and Cornwall Paint Co., Ltd., Poole.—Reg. July 3, two charges, to Barclays Bank, Ltd., securing all moneys due or to become due to the Bank.

Flinn and Son, Ltd., Fishergate, dyers.—Reg. July 4, £1,400. mort., to Sir B. S. Johnson, Abbots Lea, Woolton, Liverpool.

Vicley and Co., Ltd., Long Eaton, dyers and finishers.—Reg. July 3, £2,000. deb., to E. Hooley, Cleve-lodge, Long Eaton.

SATISFACTIONS.

Aspley Colour Printing Co., Ltd., Nottingham.—Satisfaction reg. July 10, £2,500., reg. Sept. 19, 1903, and Dec. 1, 1904.

Reparo, Ltd., London, S.E., cement manufacturers.—Satisfaction reg. July 10, £700., reg. Feb. 22, 1922.

Stella Gill Coke and By-products Co., Ltd., London, E.C.—Satisfaction reg. July 9, £30,000., reg. Oct. 3, 1922.

BANKRUPTCY INFORMATION.

Wheatly, Albt. Edwd., 170, Lord Street, Southport, late trading as a dealer in essences and bakers' sundries as Confectioners' Colour and Essence Co., 20, Wood Street, Liverpool; trav. 1st meeting, O.R.'s Liverpool, July 25. Examination, C.C. Liverpool, Aug. 21.

Hunter, Archibald Duncan, 28, Vereker Road, West Kensington, analytical chemist. Receiving Order rescinded and Petition dismissed, June 27, it appearing to the Court that all debts have been paid in full.

LIMITED COMPANIES. — Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions; Orders; and Official and Other Notices.

Cardiff Alkali Co., Ltd.—Resolved May 31, confirmed June 27: That the Company be voluntarily wound up. G. A. Knowles, liquidator.

Graham and Cope, Ltd., Dewsbury, chemical manufacturers.—H. Brooke, Market Place, Dewsbury, appointed receiver. Dec. 27, 1922.

London Hygienic Chemical Co. (1922), Ltd., London, E.C.—E. C. Gardner, Woodridings, Cumnor Road, Sutton, appointed receiver. June 28.

DISSOLUTIONS OF PARTNERSHIP.

(Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.)

Magic Wash Co. (Jno. M'Nichol), 25, Rodney Street, Glasgow, washing powder manufacturer and merchant. Business sold and transferred, as at June 15, to Jas Crabbe. J. M'Nicol will discharge all liabilities due by the firm and J. Crabbe will uplift all debts due to the firm. July 10.

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

Shepperley's Manufacturing Chemists, Ltd., 43, Chancery Lane, London, W.C.; £22. 14s. 11d. May 10.

Blunt, W. H., and Son., 70, Snow Hill, Birmingham; wholesale chemists and druggists; £13. 3s. 8d, June 4; £14. 19s. 6d., June 12.

REPORTS OF COMPANIES.

British Cyanides Company, Ltd.

The annual general meeting was held in London on Wednesday of last week, Mr. G. F. Rowsell (the chairman) presiding.

The Chairman, in moving the adoption of the report and accounts, said. After very careful consideration, your board decided to carry forward the whole of the profits made during the year under review. At the same time they decided that, provided the next one or two months do not depart from the normal to any great extent, they would declare in the early autumn an interim dividend of 5 per cent. on account of the profits of the current year.

Sir Arthur Duckham seconded the resolution.

Mr. Kenneth M. Chance (managing director) said: The fixation of atmospheric nitrogen as it concerns this company has two stages. The first stage is where we can obtain from the nitrogen of the atmosphere raw material in unlimited quantities for the cyanogen products which we manufacture. The second stage will be when we can fix atmospheric nitrogen at a sufficiently low cost to convert it into ammonia at a price which will enable us to compete with any other method of manufacturing ammonia. It has been obvious now for many months that we were rapidly approaching the first stage, and, on the recommendation of the General Staff Committee, the board have to-day given instructions for estimates to be prepared for a plant for manufacturing cyanogen from the nitrogen of the atmosphere. The second stage to which I have referred is one which can only be reached gradually, but we have two plants in course of erection, each of which is a practical working unit, and the prospects of being able to fix the nitrogen of the atmosphere at exceedingly low cost in both these plants are excellent.

We have now overcome the last difficulties in respect of the manufacture of permanganate of potash by electrolysis, and new plant for the manufacture of that chemical is in course of erection at the Tat Bank works and should be in operation very shortly after the holidays. Our new works scale experimental house has also enabled us to prove out the manufacture of another chemical for which there is a good market, and it is only a question of time before we shall add this to the growing list of new processes that we are establishing; but I expect that the opening up of the permanganate plant and that for the fixation of atmospheric nitrogen will keep us rather too busy to take up any other work for the next few months.

The resolution was carried unanimously.

Major and Company, Ltd.

The annual meeting was held in Hull on Thursday of last week, Mr. J. L. Major (chairman of the company) presiding.

The Chairman, in moving the adoption of the report and accounts, apologised for the delay in presenting the accounts, and stated that it was possible that the accounts would in future be made up to March 31. Continuing, the Chairman said: We have, as you have already been informed, reconstituted our Tarslag business as a public company, providing that company with considerable additional funds. The issue was underwritten. The old company will receive £55,000. in cash and £70,000. ordinary shares out of £100,000. issued. After a deduction of certain payments to balance the old accounts, Major and Co. will receive the whole of the residue.

Our patent continuous still, which I mentioned last year, has now been adopted as far as possible for all our distillation purposes, and gives a considerable economy. We have not pushed it outside our own business to any extent, as we wish to gather all the experience and information regarding it in our own works, so that we can offer a perfect plant elsewhere. The still is patented in various foreign countries, including the United States. We have inquiries for the plant from the United States, and there are people there who are anxious to take it up.

Our dyestuffs department has been a very serious cause of anxiety, but we see a good time coming, and I do not think we shall regret having kept to it. We have confined ourselves to a limited range of pigment colours. I believe that there is a good future in front of the British dyestuffs industry if the Government continues with the very necessary, though tardy, support which is now given by the Dyestuffs Act. It would be a shameful thing if all the money and brains that have been poured forth to establish the industry in this country were wasted by a return to unrestricted imports, under the conditions prevailing in Europe to-day. When working conditions again become normal—it seems a very far away proposition at present,—I for one should have no fear of fair German or any other competition.

According to the report, the profit for 1922 was £30,403. (against £25,761 for 1921), while £2,140. was brought forward. It is proposed to pay a final dividend of 4½ per cent. on the preferred ordinary, making 8 per cent. for the year, and a dividend of 10 per cent. on the ordinary shares (the same). A sum of £2,443. is carried forward.

Mond Nickel Company, Ltd.

The annual general meeting was held on Thursday of last week. The Right Hon. Sir Alfred Mond, presiding, said that the credit balance to profit-and-loss account for the past three years was: In 1921, £222,000.; in 1922, £209,000.; and in 1923, £307,000.; which showed a recovery in the affairs of the company which everyone must think very satisfactory in the present disturbed state of trade. The demand for nickel, which had been at a very low ebb, had sustained a very considerable improvement during last year, an improvement which at present was maintained, and their turnover and deliveries had been satisfactory. Their products had been increased and their works were well employed, but the prices which had been ruling, owing to a somewhat unrestricted competition from a good many sources, had been lower than at almost any other period of the industry, and had counteracted to some extent the benefits derived from the larger sale and the larger production. Copper sulphate, of which they were the largest manufacturers in the United Kingdom, and which was the product which was chiefly exported to the Continent, had suffered not merely from competition, but also from severe fluctuations in the exchanges in most of the bigger export markets, such as France and Italy.

The Chairman proceeded to draw attention to the changes which had taken place in the uses of nickel during the war. Previous to the war, he said, probably 50 per cent. of their nickel had gone to steel makers for armaments and 50 per cent. for the production of non-ferrous alloys and pure nickel products, whereas last year only 12½ per cent. had gone to the former and 87½ per cent. to the latter. The use of nickel for coinage was increasing, many countries now replacing their paper currency with nickel; the use of nickel for cooking utensils was also on the increase.

The report and accounts were unanimously adopted.

Anglo-Continental Guano Works, Ltd.

Net profit for 1922, after providing for all trade charges, directors' fees, and doubtful debts, was £24,314., less income tax, corporation tax, and interest on instalments in respect of debenture issue, leaving £22,971., plus £5,530. brought forward, making £28,501. Preference dividends absorb £22,500., leaving £6,001., which directors recommend be carried forward.

DIVIDENDS.

United Alkali Co., Ltd.—Interim dividend of 4 per cent. actual, less tax, which is equivalent to 6 per cent. on the old share capital.

NEW COMPANIES.

Orient Company, Ltd.—Capital £52,575., 6s. shares. Manufacturers of vegetable products, oil extractors, etc. Office: Orient House, 21, Budge Row, London, E.C. 4.

Artificial Silk and Textile Company, Ltd.—Private company. Capital £10,000. Office: 64, Basinghall Street, London, E.C.

De Vains Process, Ltd.—Private company. Capital £5,000., £1. shares (4,500 A and 500 B). Manufacturers of paper pulp, cellulose, etc. Solicitors: J. D. Langton and Passmore, 57½, Old Broad Street, London, E.C.

Liquid Oxygen Explosives, Ltd.—Private company. Capital 31,500., in 30,000 ordinary of £1. and 30,000 founders' shares of 1s. Office: 1, Albemarle Mansions, Albemarle Street, London, W.

Giffen Chemical Company, Ltd.—Private company. Capital £3,000. Solicitors: Onderson, Fyfe and Littlejohn, 201, West George Street, Glasgow.

Thornley Binders, Ltd. — Private company. Capital £100,000. Manufacturers of products from seaweed and waste products, etc. Solicitors: Ashurst, Morris, Crisp and Co., 17, Throgmorton Avenue, London, E.C.

FERTILISER NEWS.

Nitrate of Soda.—As is usual at this time of the year, the market for nitrate is very quiet, with little business about. Shipments for the first half of the month totalled 110,000 tons, of which 63,000 tons were to Europe, 41,000 tons to the United States, and 6,000 tons to Japan and other countries. This compares with 68,000 tons in the corresponding period of 1922, 12,000 tons in 1921, and 61,000 tons in 1914. The heavy sales made by the Association for the current year have been the cause of much congratulation in the daily Press, and holders of nitrate shares have been encouraged by the promising outlook. But the inevitable has happened, and resales reported to be upwards of 25,000 tons have already been made. This material, contracted for at the lower range of the graduated price scale for August-October delivery, is now being sold by speculators at the rate of 20s. 5d. per metric quintal, or just 2d. per quintal under the figure of 20s. 7d. for November delivery, which is the cheapest price at present offering by the Association. This sort of thing is bound to affect the first-hand sales, and it is possible that with the extremely heavy rush to buy on the announcement of the new price list, this aspect of the nitrate market will be more evident than ever. In any case, the situation is such that the producers have been able to dispose of only 8,000 tons during the first half of July. If this slackening-off in orders continues it is difficult to see how the Association can pretend to maintain prices at the existing rates for forward delivery. It is understood that there is yet about 35,000 tons of material available for November shipment, but whether the 20s. 7d. to 21s. quotations will stand, remains to be seen. European stocks, including material afloat for the Continent, amounted on the 15th inst. to about 214,000 tons, against 238,000 tons at the same date of last year. So far as the position on the other side of the Atlantic is concerned, prices have again been generally advanced, both for spot and forward business, by about 5 cents per 100lbs. The general opinion seems to be that this is an effort to secure orders by creating the impression that the market was advancing. Little business has resulted from this manœuvre, however, and most consumers are buying from hand to mouth, though stocks in dealers' hands are of fair dimensions.

Sulphate of Ammonia.—The effects of the new and lower prices for this fertiliser in the home market are beginning to be apparent, and increased inquiry and better business is reported. Even at the attractive prices now ruling, however, there is still much hesitation amongst agriculturists owing to the difficult conditions. The definite proposals put forward in the House of Commons, and the evident anxiety to do something to assist the farming community in this country, may cause a reaction in favour of a more extensive use of fertilisers, which means a revival in the demand for home-produced sulphate. The official figures for exports of sulphate from the United States show a marked falling-off in the past few months, and it is evident that the world markets for some time to come will be open to United Kingdom manufacturers. On the Continent quotations are equivalent, at current rates of exchange, to from 25s. to 15s. below the price fixed by the Federation for home consumption. The seizure of the stocks of nitrogenous fertilisers, chiefly ammonium sulphate, by the French in the occupied area has resulted in a general weakening of the price in that country, and the quotation at which the French organisation has been doing business is round about £12. per ton. The rapid distribution of this material is bound to be followed by a scarcity, when prices will inevitably rise to a level at which British sulphate can once more be imported in quantity. Exports of sulphate from this country to France have been steadily falling off month by month, but the possibilities of large supplies from elsewhere are now very remote. In Germany the prices of nitrogenous products have again been raised, but figures in terms of German currency are meaningless to-day, and quotations would need to be revised almost hourly to keep pace with the receding value of German credit.

Egyptian Phosphate Industry.—In 1913 the production and exportation of phosphate from Egypt promised to result in an industry of considerable importance. During the past three years, however, a sharp decline has occurred, states an American consular report, although the average value per ton in 1922 shows an increase in comparison with 1921, and is more than 100 per cent. greater than the average value in 1913, when over 64,000 tons of phosphate were exported, mainly to Japan. In 1920 exports reached almost 145,000 tons, with Japan as the principal buyer, closely followed by Italy and British possessions in various parts of the world. During that year the average price per ton to Japan was considerably higher than to other customers. During 1921, in spite of a sharp price decline, the total exports amounted to only a little over 84,000 tons. In that year Spain was the principal buyer, followed by Japan, Italy, and Portugal in the order named. In 1922 exports amounted to only 18,000 tons, or approximately only 25 per cent. of the exports of 1913. Italy was the main purchaser, taking almost half of the total exports, with the United Kingdom and Japan dividing the remainder.

General Notes.—The British Phosphate Commission of Nauru, in its annual report for the year ended June, 1922, states that the tonnage of cargoes shipped was 360,000, of which Australia received 47 per cent., New Zealand 10½ per cent., Great Britain 4½, and other countries 38 per cent. All Empire demands were met at satisfactory prices, and the surplus was disposed of to foreign countries at market rates. The results of the first two years rendered possible substantial reductions in the selling price for the third year. The trading account shows a credit balance for the year of £91,000.

It is announced that a factory for the production of synthetic ammonia by the Claude process is to be erected in Spain in order to utilise the production of hydrogen at the electrolytic soda works of the Société Electroquimica de Flix.

Of the 18,300 tons of sulphate of ammonia imported into France during the first three months of 1923, 13,005 tons came from Great Britain, 1,983 tons from Germany, 1,226 tons from the Sarre province, 653 tons from Belgium and Luxemburg, and 1,433 tons from unspecified countries. For the same period of last year, 31,780 tons were imported, and 13,581 tons in 1921.

Superphosphate prices in Holland, to which allusion was made in our issue of June 1 last, were incorrectly quoted, owing to a typographical error in a correspondent's report. The current prices should have been given at 25fl. to 27.50fl. per ton for 30% grade, instead of the quotations given.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

One satisfactory feature of the hematite pig-iron trade, now in a very depressed condition, is that so far, the production of ordinary iron, in the smelting of which local coke is largely if not entirely used, has not been curtailed as has that of the low-phosphorus iron. There are still five furnaces blowing in West Cumberland that are smelting ordinary iron, and there are two furnaces at Barrow that are producing for steelworks consumption. A further reduction of iron output in this district that has taken place this week scarcely affects the coking industry. How long the furnaces at Workington will continue in full blast is not of course known, but it is hoped that here at all events it may not be necessary either to blow furnaces out or to damp them down. The outlook in the hematite pig-iron trade, it must be admitted, is not very encouraging. The depreciation in values has not apparently helped matters at all. Bessemer mixed numbers are now at £5. 15s. per ton delivered at Glasgow and Sheffield, and ordinary iron is in even less active request than it was a week ago. It is, however, the demand for East Coast coke and not that for local coke that has slackened off. East Coast coke supplies this week are not 7,000 tons, while practically the whole of the make in West Cumberland is being absorbed by smelters. That the position would have been somewhat different if the Whitehaven ovens had been in operation goes without saying. The collieries at Whitehaven, however, are still idle, and there does not appear to be the slightest prospect of their resuming work. To local smelters the price is now 29s. to 33s. per ton. Scotland is taking a small part of the make at 34s. per ton, and what coke is going to the Continent is being sold at 34s. to 40s. per ton. The make of tar is all being taken by the chemical works on the coast. Sulphate of ammonia is moving away satisfactorily, but crude benzol, since the price dropped, is a slower trade. Creosote is steady and some portion of the make is being exported. Tar acids are fairly firm, but road tar is quieter. Sulphuric acid is in fair demand.

PARLIAMENTARY NEWS.

Smoke Abatement Bill.

In the House of Lords on Thursday, July 19, the Earl of Onslow introduced the Smoke Abatement Bill, the object of which is to amend the law relating to smoke nuisances. The Bill was read a first time.

Industrial Alcohol Production.

In the House of Commons, on Wednesday, July 18, Mr. Hardie asked the President of the Board of Trade: Whether, in view of the fact that we are dependent on outside sources for a supply of liquid fuel, he will consider the question of immediately developing the manufacture of industrial alcohol in this country?

Viscount Wolmer: This question is discussed in the Interim Memorandum and Second Memorandum by the Fuel Research Board on Fuel for Motor Transport, published by His Majesty's Stationery Office in 1920 and 1921, respectively. Investigations by the Fuel Research Board are still proceeding with a view to discovering a suitable method of manufacturing alcohol from materials available in this country and in the Empire.

Mr. Hardie: Is not the Noble Lord aware that, with the knowledge that we have now, there is no need for any further investigation, but that we can go on and make industrial alcohol; and will his Department, in the interests of the trade of this country, see that the plant is allowed to work continuously instead of intermittently, and thereby make this country the equal of other countries in this respect?

Viscount Wolmer: I am sorry to say that the Fuel Research Board do not agree with the views of the hon. member.

Overalls for Oil-mill Workers.

Mr. Rhys Davies on Monday (July 23) asked the Home Secretary: Whether he will cause inquiries to be made into the operation of Order No. 959, factory and workshop welfare, in respect of the oil-mill workers employed by Messrs. Lever Brothers, in the Birkenhead area; whether he is aware that a claim made on behalf of such workers for protective clothing by way of overalls, agreed upon by employers and workpeople in the industry, has been ignored by the firm in question; and whether he will take the matter up with the firm so that the Order may be carried out in every detail and according to the custom prevailing in that district?

Mr. Bridgeman: I have no information at present in regard to the matter referred to in this question. Inquiries will be made and the result communicated to the hon. member.

SOUTH WALES NOTES.

[Specially Contributed.]

The tinplate industry does not show much promise of improvement, and such business as is now being done is on a small scale for quick delivery. The figures relating to exports for the half-year ending June 30 reveal a partial recovery, there being an increase of some 62,000 tons over the corresponding period of 1922. The increase is accounted for by greater export trade to Holland, France, Italy, China, Japan, Argentine, India and Australia. In June, there was an increase of 13,000 tons as compared with June last year, with a larger gain in values owing to the higher prices obtained. There was also a steady improvement in the galvanised sheet trade, an increase of some 12,500 tons over last year being shown. In this case, the Colonies were the chief factor of the improvement. Inquiries for patent fuel are more numerous and business is steadily improving, apart from the usual seasonal dulness. There is no alteration in the copper trade, smelting establishments now working having to stock the metal, although by-products are in fair demand. Cokes are in much better request, and orders have been received that will occupy many ovens over the remaining half of the year.

The imports for the week to Cardiff included 312cwt. barytes from Hamburg, 705cwt. phosphorus from Montreal, 5 tons manganese ore, and 103cwt. red lead from Antwerp, 3,560cwt. glucose from New York, 277 tons burnt ore from Wicklow; to Swansea, 7½ tons zinc ashes from Montreal, 80 tons copper ore, 207cwt. red lead from Genoa, 5,535 tons pitch from Pensacola, 3 tons tin oxide from Rotterdam, 7 tons lead ashes from Antwerp; 50 tons silicate of iron, 25 tons calcium carbide from Christiania; to Newport, 1,895 tons iron pyrites from San Juan. The Cardiff exports included 460 tons pitch to Antwerp, and 960 tons sulphate of ammonia to Galway; from Newport, 109 tons ammonium nitrate to Antwerp.

THE COLOURING OF POISONS.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—May I, as an analytical, dispensing, and manufacturing pharmaceutical chemist, with some forty years' experience in these various branches, be allowed to reply to Mr. Sexton's letter? I would submit that in the matter of "Colouring poisons for medicinal use" no one, without a practical knowledge of the subject, is qualified to give an opinion for or against, and a debate in the House of Commons by members, the majority of whom would be entirely ignorant of the subject debated, would be either useless or, possibly, very dangerous.

I entirely agree with the decision of the General Medical Council. "A preparation of strychnine" mentioned I presume to be the "liquor strychnine" of the B.P. (a solution the official strength of which is, roughly, one per cent). To colour this green certainly would be objectionable in many ways, and would be no safeguard against carelessness. If carelessness occurs with a colourless preparation it will occur with a coloured one. The novelty of being coloured would soon wear away. But the greatest difficulty in legislating would be drawing the line as to what is "a preparation of strychnine." Take the hypodermic tablets of varying strengths. To introduce colouring matter into these would be as unscientific as colouring distilled water. Then Mr. Sexton cannot be aware that there are, besides the preparations of nux vomica, many others prescribed containing strychnine the natural colour of which would make it impossible to colour "green." I could enlarge considerably on the subject, but I have probably drawn sufficient attention to the difficulties to show that it is not a matter for men without the necessary qualifications to meddle with.—Yours, etc.,

Geo. D. Yates.

Birkenhead, July 20.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, whence, unless otherwise stated, further information may be obtained.

Norway.

An agent in Christiania is desirous of securing the representation in Norway of a British manufacturer of boiled linseed oil. (Ref. No. 70.)

A firm of agents in Christiania are desirous of securing the agency in Norway of a British merchant supplying agar agar. (Ref. No. 73.)

United States of America.

A firm of manufacturers' agents in San Francisco wish to communicate with British manufacturers of coal tar products, lithopone, zinc oxide, whiting—lump or ground, barium carbonate and barium sulphate, and with producers of china clay, with a view to obtaining agencies for the Pacific Coast of the United States. They are prepared to act on a commission basis or would finance own stocks. (Ref. No. 83.)

A firm of chemical manufacturers and merchants in San Francisco wish to communicate with British exporters of shellac and varnish gums with a view to obtaining an agency, on a commission basis, for the Pacific Coast of the United States. (Ref. No. 86.)

Hong Kong.

A firm of Hong Kong importers are desirous of getting into touch with United Kingdom exporters of sulphate of ammonia. (Ref. No. 11,121/F.E./C.C.).

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

July 9 to 14 (inclusive).

Intermediates and Dyestuffs. Barnard, C. M. 17,821.
Dyestuffs. Barnard, C. M. 17,822.
Azo Dyestuffs. Bloxam, A. G. (*Chemische Fabrik Griesheim-Elektron*). 18,008.
Sulphuro-phosphate Bodrero, B. 18,087.
Toilet Soap. Clifford, W. 18,137.
Drying-kilns. Cutler, C. A. 17,891

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Regenerating Rubber with Acetylene. J. C. Koller, Johannesburg, South Africa. British Patent, **198,067,** of 1922.

The resiliency of vulcanised rubber, etc., is restored, preserved or enhanced, or the plasticity of unvulcanised rubber is increased by treatment with acetylene. Perished vulcanised rubber is comminuted and washed with water or caustic solution to remove impurities and swell the rubber, and is then placed in an atmosphere of acetylene for about two weeks, and is finally washed with hot water. The resulting powder is capable of revulcanisation. The resiliency of rubber articles is restored or increased by the same treatment. Raw rubber is first treated to swell it and is then immersed in the acetylene. The acetylene is preferably generated by adding a solution of a carbohydrate to calcium carbide.

Ultramarine. E. F. Kur, Bognor, Sussex; and F. Wilkinson, Bradford. British Patent, **198,212,** of 1922.

Ultramarine is formed by heating to 700°-1,000° C. a mixture of calcined china-clay and an alkali polysulphide other than a polysulphide of ammonia. In an example, 30-40 parts of calcined china-clay free from iron and lime are mixed with 15-30 parts of sodium trisulphide and the mixture heated for at least six hours.

Active Carbon. Count L. le W. Hamon, Ballycumber, King's County; and T. H. Byrom, London. British Patent, **197,971,** of 1921.

Peat, lignite, sawdust or other carbonaceous material is saturated under pressure or otherwise with a metallic salt solution and a soluble phosphate, carbonate and/or silicate is added to precipitate in the pores of the material an insoluble phosphate, etc. The material is then carbonised and soluble matter extracted. In an example aluminium sulphate and magnesium and calcium chlorides are given as suitable salts and phosphoric acid as the precipitant. Hydrochloric acid, with or without heat, is used to extract the soluble matter after carbonisation, and the carbon is subsequently dried. The salts obtained in the extraction may be employed in the impregnation of fresh material.

Treatment of Animal Fibres with Acetic Anhydride. R. B. Ransford, London. (Cassella and Co., Ges., L., Frankfort-on-Main, Germany.) British Patent, **198,166,** of 1922.

In the production of shot effects, animal fibres are treated with acetic anhydride. The treatment may be effected cold or hot, and may be accelerated by the addition of aromatic sulphonic acids, condensation products thereof with aldehydes, free mineral acids and their salts with weak bases, for example, aluminium sulphate or dimethylaniline sulphate. Where the material is intended to be interwoven with white yarn, the material after dyeing is treated with a chromium salt such as chromium fluoride.

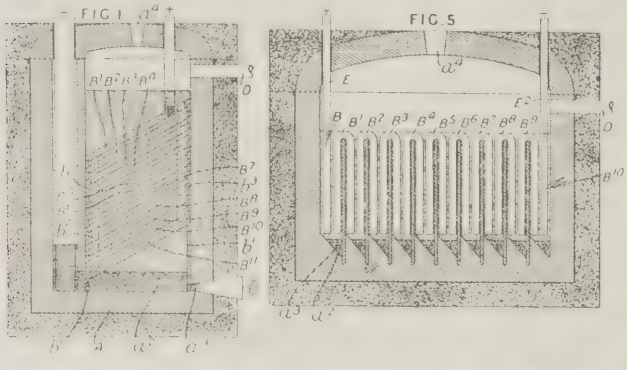
Rubber Containing Bituminous Compositions. A. C. de Caudemberg, Nice, France. British Patent, **198,136,** of 1922.

India-rubber is incorporated with asphalt, bitumen, pitch, etc., by means of liquids of high boiling-point which are solvents for india-rubber and bitumen. Suitable solvents are mixtures of tetrachlorethane with benzene or toluene containing 20 per cent. of tetrachlorethane for cold preparations and 86 per cent. for hot ones. An asphalt composition to be compressed cold is obtained by mixing in the cold 100 parts of powdered asphalt with 3-4 parts of a solution containing 2.5-5 per cent. of rubber. An asphalt to be used in

a fused condition is made by melting together 100 parts of asphalt, 5 parts of bitumen, and 4-5 parts of a solution containing 5-7.5 per cent. of rubber, with or without the addition of sand or gravel.

Electrolysis of Fused Salts. E. A. Ashcroft, London. British Patent, **198,024**, of 1922.

The electrolysis of fused metallic salts, such as fused chloride of zinc or lead, or a mixture thereof, is effected in an electrolyser provided with a series of closely-spaced electrodes constituting a series of electric couples immersed in the same electrolyte, only the first and last of the electrodes of the series being connected to the external circuit. Fig. 1 shows an electrolyser comprising a refractory container A, or a metal container lined with refractory material, surrounded by a casing of kieselguhr. The electrodes consist of a number of inclined graphite plates B^1 . . B^{11} resting on steps b of fused silica, vitreosil or obsidianite, the steps b^1 for the lowest plate being of graphite. Fused zinc chloride is introduced through an opening a^4 at about 350° to 400° C. and the temperature of the electrolyte is maintained between 420° and 600° C., and preferably between 450° and 500° C., during electrolysis. This may be done by applying external heat in the form of



a jacket through which superheated steam, hot air, or hot oil is circulated, by supplying a supplementary alternating current, or by supplying more direct current than is necessary for electrolysis. Zinc flows downwards through the perforations b^2 in the electrodes to the reservoir a^2 which is provided with a tap-hole a^3, and chlorine passes up through the perforations b^3 to the outlet D. A suitable proportion of sodium, or potassium or magnesium chloride may be added to the electrolyte to increase its conductivity. In a modification the electrodes consist of funnel-shaped plates through the centre of which passes a silica tube containing a graphite negative conductor. Fig. 5 shows an electrolyser with a number of saddle-shaped electrodes B^1 . . B^9 mounted on refractory partitions, the end electrodes B, B^{10} being connected directly to carbon rods E, E^2 which supply the current. The zinc gathers in a number of separate compartments a^2 having outlets a^3. The saddle-shaped electrodes may be replaced by graphite plates mounted in grooves in the sides of the container A. In every case the electrodes may be corrugated or grooved as desired. The current density used is 2 amps. per square inch of electrode surface. Metallic ores and other metal bearing materials are chlorinated and then subjected to the above process to obtain the pure material. Specifications 15649/92 and 8894/00 are referred to.

Anthraquinone Vat Dyestuffs. R. B. Ransford, London. (Cassella and Co., Ges., L., Frankfurt-on-Main, Germany.) British Patent, **193,077**, of 1922.

Vat dyestuffs, which are most probably oxazoles and thiazoles of the anthraquinone series are obtained by condensation of the azomethine compounds derived from anthraquinone-2-aldehyde or a substitution product thereof, and an *o*-aminophenol, or an *o*-aminothiophenol or an equivalent thereof respectively; the condensation is effected by heating alone or with a solvent, and with or without a condensing agent such as sodium acetate, zinc chloride, or sulphuric acid. A mixture of an anthraquinone-2-aldehyde with an *o*-aminophenol or an *o*-aminothiophenol may also be condensed directly to the dyestuff without isolation of the azomethine compound. Equivalents of *o*-aminothiophenols are aromatic amines sulphurised in the ortho position such as *o*-diaminoaryldisulphides, *o*-aminoarylthiosulphonic acids and particularly the substances described in Specifications 17417/14 and 18292/14 derived from the action of disulphur dichloride on primary aromatic amines, and their products of transformation.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Sulphuretted Vat Dyestuffs. H. Pereira, Vienna. British Patent, **197,932.** Convention date, May 18, 1922.

1:12- Dioxyperylene is heated with sulphur or alkaline sulphides or alkali hydroxides and sulphur. The product dyes cotton brown to black shades from a hydrosulphite vat.

Enamels. Chemische Werke vorm. Auerges, Berlin. British Patent, **197,933.** Convention date, May 18, 1922.

To prevent opaque enamel from bubbling during firing, a portion of the clay which is usually added to the mill is first made incandescent and then added to the other ingredients. One-half of the clay may be so treated, and the process is stated to be particularly applicable when zirconium or cerium oxide is present.

Catalytic Decomposition of Water Vapour. C. E. Laurent, Seine-et-Oise, France. British Patent, **197,647.** Convention date, May 13, 1922.

Water vapour is decomposed into its constituent elements by passage at temperatures of 125-400° C. over a catalytic material comprising a mixture in suitable proportions of (1) a substance of the class of "metallic poisons," such as salts of arsenic, mercury, silver, phosphorus, barium, sulphur, selenium, tellurium, boron, cyanides, and oxalates; (2) carbon in the form of graphite, coal, coke, etc.; with (3) a metallic salt of lead, zinc, tin, antimony, bismuth, or alumina, silica, magnesia, etc. The catalytic mixture, examples of which are given, is preferably made up into small balls or into a porous mass. The water vapour, prior to its catalytic decomposition, may be mixed with a small quantity of carbon-containing substance, such as gasoline, alcohol, benzine, acetylene, illuminating gas, and in general, all hydrocarbons and inflammable gases; the resulting gaseous products are useful for lighting, heating, and as a motor fuel.

Rubber Vulcanisation Accelerators. Naugatuck Chemical Company, Naugatuck, Connecticut, U.S.A. (Assignees of S. M. Cadwell, Leonia, New Jersey, U.S.A.) British Patent, **197,632.** Convention date, May 15.

The reaction product of an open carbon chain aldehyde having more than two and less than eight carbon atoms in the chain, and ammonia, is used as an accelerator in the vulcanisation of rubber, etc. Suitable aldehydes are heptaldehydes, propionaldehyde, cinnamylaldehyde, isovaleraldehyde. Specifications 7370/14 and 180,978 are referred to.

Ammonia Synthesis. L. Casale, Rome. British Patent, **197,655.** Convention date, May 13, 1922.

To avoid overheating of the catalyst in the synthesis of ammonia, the reaction gases are passed over the catalyst along with a predetermined quantity of the reaction product. This is preferably effected by withdrawing only a part of the ammonia as it is formed, the remainder being allowed to circulate with the reaction gases. The ammonia synthesis may take place under any pressure conditions and catalysts may be used which are active at temperatures lower than those usually employed.

Fertilisers. Soc. d'Etudes Chimiques pour l'Industrie, Geneva. British Patent, **197,690.** Convention date, May 15, 1922.

A fertiliser is made by treating a porous material such as peat or turf, clay, pozzuolana, or other volcanic ash, with a concentrated solution of cyanamide, obtained from calcium cyanamide, and drying the mixture in air. When peat or turf is used the fertiliser contains urea. Previous to the drying the mixture may be heated in the presence of nitrogen, oxygen, air or carbon dioxide, or of a mixture

of these gases, to a temperature preferably between 60° and 90° C. and not exceeding 120° C. and under a pressure of 5 to 25 atmospheres. When peat is used the treatment may be repeated with a view to increasing the nitrogen content of the final product.

Colloidal Solutions. Oderberger Chemische Werke Akt.-Ges., Oderberg, Czecho-Slovakia. British Patent, **197,966.** Convention date, May 19, 1922.

Sols are produced by mechanical dispersion of a substance in the dispersion medium in presence of the usual protective colloid and in addition an electrolyte preferably in the proportion necessary to precipitate the sol, if it were at rest. In examples crude sulphur and lamp-black respectively are colloidalised in water in presence of glue and common salt. It is stated that sols of almost any desired concentration are thus obtained, which are only coagulated by extremely strong alkalies or acids. The sols may be further concentrated by treatment in a centrifugal apparatus and may be carefully dried to produce reversible gels.

Benzoquinone Mordant Dyestuffs. Durand and Huguenin Akt.-Ges., Basle, Switzerland. British Patent, **197,940.** Convention date, May 20, 1922.

Benzoquinone dyes which dye and print on chrome-mordanted wool or cotton in violet to blue shades are prepared by warming with concentrated sulphuric acid a quinone dianilide obtained from one molecular proportion of chloranil and two molecular proportions of *p*-aminosalicylic acid, or a homologue or derivative thereof such as *p*-amino-*o*-cresotinic acid or nitroaminosalicylic acid (OH : COOH : NO_2 : NH_2 = 1 : 2 : 6 : 4); instead of commencing with nitro-*p*-aminosalicylic acid the condensation product from non-nitrated *p*-aminosalicylic acid and chloranil may be warmed with nitrosulphuric acid to effect nitration and formation of the new dyestuff simultaneously, or the heating with sulphuric acid may first take place followed by addition of nitrosulphuric acid to effect nitration. The condensation of *p*-aminosalicylic acids with chloranil is effected in aqueous suspension in the presence of sodium acetate. Examples are given of the various methods, together with tables of properties of the resulting dyestuffs.

Agglomerating Fuel. H. Du Boistesselin and O. Dubois, both in Rouen; F. W. Tabb, Paris; L. Varnier, Rouen; and L. Hertenbein, Levallois-Perret, Seine, all in France. British Patent, **197,639.** Convention date, May 12.

In agglomerating powdered material, particularly fuel dust, by means of pitch, a pseudo-solution of pitch and water, for example in equal quantities, is mixed with the material and the mixture pressed and dried, preferably at a temperature—*e.g.*, 200-250° C., which ensures the removal by evolved steam of volatile products of the pitch. In one method, pitch is ground with water as the dispersing agent. Small amounts of gummy or resinous substances, such as dextrin, resin soaps or concentrated extracts of sulphite cellulose may be added to the water, and oxidising agents such as chloride of lime or nitrates of metals having two degrees of oxidation such as iron, chromium, cobalt, etc., may be introduced into the pseudo-solution before it is mixed with the fuel dust in order to oxidise oils contained in the pitch and promote the combustion of the fuel.

THIRTY-FIVE YEARS AGO.

(From the " Chemical Trade Journal, July 28, 1888.)

Cheshire Salt Combine.—On Thursday afternoon the 12th inst. a well attended meeting of the salt trade was held at the Adelphi Hotel, Liverpool, for the purpose of meeting Messrs. W. H. Fowler and Co., solicitors, of London, as the representatives of a syndicate of London financiers who are desirous of purchasing the whole of the salt interests in Cheshire, with the idea of forming one large company. With one or two exceptions, the entire trade was represented, and the meeting was practically unanimous in its determination to assist in the formation of a company which should do away with the present most wretched state of the trade. It has been known for some time that the prices many salt makers have realised for their manufactured article has been much less than the cost of production, and the salt manufacturers present at the meeting at the Adelphi Hotel seemed to think that such an opportunity of putting the trade on a satisfactory basis had never before occurred, and that if the opportunity was let slip it was not likely to occur again for many years. It has been stated that the purchasers are displaying the utmost willingness to meet the vendors in a spirit of liberality and equity, and are prepared to give a satisfactory price to all parties for everything they have to sell having an element of value in it, that is capable of earning or being accessory to earning money. At the meeting in question an arrangement was entered into by which each salt proprietor or manufacturer was to send in within one week the value which he places upon his works, flats, steamers, wagons, and everything used by him in carrying on his business. This will be submitted to Messrs. Fowler and Co., and it is believed that an arrangement will be made which will be satisfactory to all parties.

MARKET REPORTS.

LONDON " OPEN MARKET " REPORT. Wednesday.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals.—Owing to the dock strike there is some difficulty in getting goods landed, and for that reason holders of spot supplies have been able to obtain their prices. However, business remains very slow in most quarters in the home trade. The demand from the textile industries seems to have ceased for the time being. **Acetic Acid,** 80% technical, £47. to £48.; 80% pure, £50.; 98% glacial, £60. in casks, and £75. in glass demijohns, ex wharf, London; there is not much offering on spot, and these prices are fully maintained. **Acetone,** British Government specification, about £120. per ton, in drums; this is a particularly firm item, and there has been good inquiry on the market. **Arsenic,** Cornish, white powdered, about £72. to £73. per ton, for small spot lots; actual business remains very small. **Alum,** lump, £10. 10s. to £11. per ton, in casks; hardly any inquiry about at present; dealers offering at these figures. **Anhydrous Ammonia,** 99.95%, about 1s. 5d. per lb.; this price is still quoted, with business dull. **Barium Chloride,** 98/100%, £15. to £15. 10s. per ton, for spot parcels; supplies are moving off but very slowly. **Bleaching Powder,** 35/37%, £10. to £10. 10s. per ton; importers are offering at about these rates for shipment, but find business very poor. **Borax,** commercial, granulated £26. 10s., crystals £27., powdered £28., extra fine £29.; B.P., crystals £31., powdered £32., extra fine £33. per ton, for home trade only, in 2cwt. free bags, carriage paid to destination; British makers' prices are unchanged. Importers are quoting under similar conditions, commercial, granulated £25. 10s., and powdered at £27. per ton. **Borax Glass,** lump £74., powdered £75. per ton, in tin-lined cases; British makers selling for home trade only, packages free, carriage paid to destination. **Boric Acid,** commercial, crystals £50., powdered £52; B.P., crystals £56., powdered £60., extra fine £62. per ton, in free bags, carriage paid to destination; British makers' prices for home trade only are unchanged; dealers are competing at about level rates. **Cream of Tartar,** 99/100%, 92s. to 94s. per cwt., less 2½%; there has been a fair demand of late, but mostly for small quantities; slightly cheaper rates are quoted for 1 ton lots. **Citric Acid,** B.P., crystals, about 1s. 7d. to 1s. 7½d. per lb., less 5%; the spot position seems rather easier and the outlook is not at all promising. **Epsom Salts,** commercial quality, about £5. per ton, in bags; there is still very little life in this market. **Formaldehyde,** 40% volume, about £96. per ton, nominal; it is very unlikely that there will be any business done in this product until

the referee's decision is published on the recent appeal case. **Glauber's Salt,** commercial quality, about £3. 15s.. to £4. per ton, in bags; this product is seldom inquired for. **Lead Acetate,** brown, about £42. to £43. 10s., white crystals about £43. per ton; dealers are doing a limited business here, with prices ruling steady. **Litharge,** pure flake, British, about £37. per ton; dealers are offering Continental material in the region of about £36. per ton. **Lithopone,** about £22. to £22. 10s. for 30% Continental red seal; a fair inquiry continues here, and these slightly easier prices govern a steady market. **Ammonium Chloride,** grey galvanising, about £30. 10s. per ton; business during the week has been very limited; spot holders are asking this unchanged figure. **Nickel Sulphate,** home trade, single and double salts, £38.; export, single and double salts, £38. per ton, carriage paid or f.o.b.; British makers quote at these unaltered prices. **Oxalic Acid,** about 6d. per lb.; inquiry remains poor and quoted rates are level on the week. **Bichromate of Potash,** about 6d. per lb.; this item is very dull, with no change in quoted values. **Carbonate of Potash,** 90/92%, about £28. to £28. 10s. per ton; 96/98%, about £32. per ton; some moderate business has been done at perhaps a shade under the quoted prices. **Chlorate of Potash,** crystals and granulated, about 3d. per lb.; no interest shown in this product at present. **Caustic Potash,** 88/92%, solid, about £32. 10s. per ton, in drums; spot supplies are available but the demand is poor. **Permanganate of Potash,** commercial quality, about 9½d. to 9¾d. per lb.; some little business has been on the market, and at the prices quoted the market appears to be steady. **Prussiate of Potash,** yellow, about 1s. 3d. per lb.; the demand for this article is still confined to small lots; prices are now steady. **Sulphate of Potash,** 90%, £11. 10s. per ton, ex ship; there is no change to record here. **Mercury,** about £10. 10s. per bottle of 75/76lbs., net; the spot position shows little change on the week, and the demand has been slow. **Red Lead,** imported, about £36. per ton; dealers offering at about this figure are doing a little business. **Salammoniac,** dog-tooth crystals £48. 10s. to £49., medium £43. to £44., fine white crystals £26. to £27. per ton; spot supplies are offering, with the demand very limited; prices seem fairly steady after the recent reductions. **Saltcake,** ground and unground, home trade, about £4. 10s. per ton; export, about £5. 10s. per ton, f.o.b.; quoted rates are unchanged on a very steady market. **Acetate of Soda,** about £25. 10s. per ton; this price is fully maintained. **Soda Ash,** 58% light alkali, £7. 12s. 6d. per ton, in bags, carriage paid to destination; British makers continue to quote at this level; their prices for export vary according to destination. **Soda Crystals,** about £5. 5s. per ton, in bags, carriage paid to destination; British makers' price for home trade only; dealers are offering Continental material at competitive prices. **Caustic Soda,** 70/72% £18. 10s., 76/77% £20. 10s. per ton, in drums, ex wharf, shipping port; dealers' prices show no further decline and business is very quiet; British makers' prices for home trade are unaltered at £19. to £21. 10s. per ton, in drums, carriage paid to destination; their prices for export vary as to destination. **Bicarbonate of Soda,** £10. 10s. per ton, in bags, carriage paid to destination; British makers' prices given; dealers are competing at about the same level. **Bichromate of Soda,** about 4½d. per lb. for home trade, and slightly more for export; British makers quote at these rates. **Chlorate of Soda,** crystals and granulated, 2⅞d. per lb.; there has been but very little inquiry on the market again this week. **Cyanide of Soda,** 98/100%, export 8½d. to 9d. per lb., home trade about 10½d. per lb.; British makers' prices given. **Nitrate of Soda,** 96%, £13. 7s. 6d. per ton, f.o.r. Liverpool; this market keeps very steady. **Nitrite of Soda,** 100%, about £26. 10s. per ton; after the slight reduction recorded last week this market is now quite steady. **Prussiate of Soda,** about 7d. per lb.; business seems very light here, and the price quoted might be shaded for good lots. **Hyposulphite of Soda,** pea crystals, about £14. 10s. per ton, in 1cwt. kegs; commercial quality, about £10. per ton, in casks; dealers' prices have eased somewhat, and the market seems irregular on quotation. **Sodium Sulphide,** 60/62%, solid about £14.; broken £15. to £15. 10s. per ton, in drums; dealers prices; little doing; 60/65% concentrated, about £15. per ton, in casks. **Sulphate of Copper,** about £26. per ton; this market has been quiet of late and prices are easier; cheap offers are being made from the Continent. **Tin Crystals,** about 1s. 4d. per lb.; the market is unchanged on the week. **White Lead,** imported, about £43. to £44. per ton; dealers are quoting steadily at about these figures, with business moderate. **Zinc Oxide,** B.P., about £51., white seal about £43.; 99.5% about £37. per ton, f.o.r. makers' works; the demand is recorded as being disappointing.

Pharmaceutical Chemicals.—The continued slackness of business is about the only matter to comment upon this week. Spot holders are quoting most products at unaltered prices, but the tone of the market is anything but good. **Acetanilid,** crystals and powder, about 1s. 5d. per lb.; the market remains dull, with prices fairly easy as quoted. **Acetyl-Salicylic Acid,** B.P., 3s. to 3s. 1d. per lb.; at these rates the spot market seems fairly steady, but business is quiet. **Benzoic Acid,** B.P., about 2s. 3d. per lb.; there has been very little inquiry of late. **Diethylbarbituric Acid,** B.P. (barbitone), about 21s. per lb.; dealers' prices are steady at this rate, but business is very slow. **Salicylic Acid,** B.P., about 2s. 2d. to 2s. 4d. per lb.; prices are now quite steady; the demand is slow. **Tannic Acid,** leviss, 3s. 3d. to 3s. 6d. per lb.; last week's easier rates hold good on a dull market. **Amidopyrin,** about 14s. per lb.; hardly any inquiry during the past week; quoted rates unchanged. **Ammonium Bromide,** 7d. to 9d. per lb.; the spot position is still irregular, with business dragging. **Benzonaphthol,** about 5s. per lb.; the market is reported idle, and quotations are unaltered. **Benzaldehyde 03,** about 3s. per lb.; business has been poor again, with prices the same. **Betanaphthol,** resublimed, about 1s. 10d. per lb.; this market keeps fairly steady, but there is little doing. **Calcium Lactate,** 1s. 11d. to 2s. per lb.; some cheaper offers are said to be on the market for good quantities. **Chloral Hydrate,** duty paid, 4s. to 4s. 3d. per lb.; at these figures the spot position seems steady. **Creosote Carbonate,** about 8s. 6d. per lb.; slightly cheaper rates are being quoted this week. **Creosote,** B.P., about 2s. 2d. per lb.; the market keeps fairly steady at this level, but business is lacking. **Guaiacol Carbonate,** about 8s. 3d. per lb.; quoted rates are level on the week, with business quiet. **Hexamine,** about 3s. 10d. to 4s. per lb.; only some small business has been on the market; quoted rates are level on the week. **Hydroquinone,** 3s. 6d. to 3s. 9d. per lb.; this item has been fairly active, with prices as quoted steady. **Methyl Salicylate,** 2s. 5d. to 2s. 6d. per lb.; these prices govern a fairly steady but rather quiet market. **Methyl Sulphonal,** about 15s. per lb.; quoted at this rate on a lifeless market. **Paraformaldehyde,** 3s. 9d. to 4s. per lb.; prices are well maintained; here and there there has been a fair call on the market. **Paraldehyde,** about 1s. 5d. per lb.; some large lots might be obtained for a shade less. **Phenacetin,** about 6s. 3d. to 6s. 6d. per lb.; these cheaper rates of last week hold good, but business very limited. **Phenazone,** about 7s. 3d. to 7s. 6d. per lb.; the market seems steadier after the declines in values recorded last week. **Phenolphthalein,** 6s. 6d. to 6s. 9d. per lb.; the spot position holds quite firm at these figures. **Piperazine,** about 4s. 6d. per oz., nominal; no business transacted. **Potassium Bromide,** B.P., crystals and granular, 6½d. to 7d. per lb.; spot supplies seem rather heavy, and there is not much demand at present; the quoted rates are varying. **Potassium Permanganate,** B.P., 10d. to 10½d. per lb.; these figures govern a much quieter market. **Potassium Sulphoguaiacolate,** about 5s. 6d. per lb.; quoted at lower levels this week on a dull market. **Salol,** 2s. 8d. to 2s. 9d. per lb.; no further decline in values is recorded, but business is slow. **Sodium Benzoate,** about 2s. 6d. per lb., nominal; the market has been idle. **Sodium Bromide,** B.P., crystals and granular, 7d. to 8d. per lb.; not much of the spot supplies seem to have been cleared and holders are showing a tendency to cut the market for business. **Sodium Diethylbarbiturate,** about 18s. 6d. per lb.; a big drop in the spot price is recorded this week. **Sodium Salicylate,** powder 2s. 4d. to 2s. 7d. per lb., crystals 2s. 8d. to 2s. 10d., pure flake 2s. 10d. to 3s. per lb.; spot holders continue to ask these rates; business has been slow. **Sulphonal,** 14s. 6d. to 15s. per lb., nominal; no interest shown in offers at these rates. **Terpin Hydrate,** about 1s. 9d. per lb.; dealers continue to quote at about these figures. **Thymol,** about 15s. per lb.; spot offers are being made, but the demand is not good.

Coal-tar Products, Intermediates, Etc.—About the only matter of interest to be recorded is a much better tone in carbolic acid crystals, which have been well inquired for for export. Other items have been generally quiet, with prices about the same. **Aniline Oil,** about 9d. to 9½d. per lb., drums free; prices show a further slight reduction on a dull market. **Aniline Salt,** about 9½d. to 10d. per lb., casks

free; there has been some little inquiry here. **Betanaphthol,** 1s. 1d. to 1s. 2d. per lb.; things are still very flat here. **Benzol,** about 1s. 7d. per gallon, f.o.r. makers' works, in buyers' packages; this product keeps in poor demand, and the quoted rate is rather weak. **Toluol,** 2s. per gallon, f.o.r. makers' works, in buyers' packages; quoted rates show no change on a dull market. **Xylol,** pure 2s. 3d., commercial 1s. 6d. per gallon, drums extra; quoted prices are unchanged on the week with business slow. **Naphtha,** about 1s. 5d. per gallon; there has been no improvement in demand, and prices are unaltered. **Solvent Naphthas,** 90/160, 1s. 5d. per gallon, drums extra; the demand is slow, but quoted rates are maintained. **Heavy Solvent Naphtha,** 90/190, 1s. 4d. per gallon, drums extra; there is no change on the week in prices, with market rather weak. **Special Oil,** for Diesels and motors, 10d. per gallon, barrels free; this product is maintained in value on a dull market. **Burning Oil,** crude, No. 3 8½d., No. 2 8d. per gallon, barrels free; no improvement in demand, and prices are unaltered. **Creosote Oil,** about 10d. per gallon, naked, f.o.b.; dealers are offering at this rate, with the market steady but not active. **Carbolic Acid,** crystals, about 1s. 2d. to 1s. 3d. per lb., f.o.b.; there has been much more inquiry this last week, and the tone of the market is considerably better; there is a decided tendency to higher rates here. **Naphthalene,** about £20. per ton; prices are maintained, although business has been slow; crude £7. to £13., crystals £21., powder about £17., balls £24., tablets £24., candles £24. per ton, packages free. **Disinfectants,** 3s. 9d. per gallon, barrels free; quoted rates show no change on the week. **Pyridine,** about 18s. per gallon; this market keeps very firm, with spot supplies difficult to locate. **Hexamethylene,** 4s. to 4s. 3d. per gallon; there is no sign of a break in this market. **Pure Methyl Alcohol,** £100. per ton, ex wharf, London; the demand has been fair and the market keeps very steady. **Pitch,** about 135s., London, spot; the market has kept steady all the week and closes at unchanged rates; good inquiry continues for forward positions, with the quotation fully 145s. to 150s. per ton.

LONDON METAL MARKET. WEDNESDAY.

Copper: Standard brands, £65. 12s. 6d. to £65. 15s., cash; £66. 7s. 6d. to £66. 10s., three months; electrolytic, £72. 10s. to £73. **Tin:** Standard, £181. 5s. to £185. 10s., cash; £186. to £186. 5s., three months; Straits, £188. 5s.; English, £186. **Lead,** soft foreign, £24. 7s. 6d., prompt; English, £26.; chemical sheet, 33s. per cwt. for 2-ton lots, delivered. **Spelter,** prompt, £30. 10s.; hard, £25. **Antimony,** English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35. **Aluminium,** 98—99%, £115. to £120.; foreign, £110., c.i.f. **Nickel,** £130., delivered; £125. to £130. for export, f.o.b. **Mercury,** £10. 2s. 6d. to £10. 5s. **Bismuth,** 10s. **Platinum,** 500s. per oz. **Wolfram,** spot, 13s. per unit, c.i.f., United Kingdom or Continent. **Zinc Dust,** quotations are as follows: Highest grade English, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET. WEDNESDAY.

The demand for heavy chemicals still continues quiet in the home trade, but rather more inquiry prevails for export account. Values, however, show no improvement, and quotations generally are in buyers' favour. Prices for **Alkali** products are unchanged at current rates, and makers fairly well engaged with orders. **Bleaching Powder,** soft-wood casks, steady at £11. 7s. 6d. on rails. Foreign supplies of **Epsom Salts** and **Magnesium Chloride** are offering at cut rates. The demand for **Bichromates** and **Chlorates** is quiet and prices are unaltered. Roasted **Saltcake** is firm at £4. 10s. in bulk, carriage paid. **Copper Sulphate** is in only small request, and quotations easy at £26., f.o.b. American **Rock Sulphur,** £5. 5s. on rails. **Phosphate** and **Hyposulphite of Soda** are neglected. **Nitrite of Soda** scarce on spot, and price firm at £26. 10s., basis 100%, ex store. Concentrated **Sodium Sulphide,** £15. per ton. White powdered **Arsenic,** steady, at £70., on rails Cornish works. **Yellow Prussiate** is only moving off slowly; **Potash** at 1s. 2¾d., and **Soda** 6¾d. per lb. **Carbonate** and **Caustic Potash** are in fair demand, and values firm. Brown **Acetate of Lime,** dearer, at £11. 10s.; grey lower, at £20. per ton. **Acetate of Soda,** in short supply, and price maintained at £24. 18s. per ton. **Lead Salts** are dull; white **Acetate** £40., brown £42.; and **Nitrate** £42., delivered. **Barium Chloride,** firm, at £15. per ton, ex store. **Oxalic Acid** is quiet, at 6d. per lb. **Permanganate of Potash,** 9½d. to 9¾d. per lb.

SWANSEA MARKET REPORT. WEDNESDAY.

Business in **Tinplates** very quiet, with no inclination among users in placing contracts; small immediate delivery orders were secured on the minimum basis of £1. 3s. 1½d. per standard box. **Galvanised Sheets** easier, on the general basis of £17. 2s. 6d. per ton. **Copper** showed a better tendency, at £65. 10s. per ton for prompt and £65. 12s. 6d. for forward. **Tin** rather dull, and quotations very irregular round £185. 17s. 6d. per ton prompt, and £187. 2s. 6d. forward. **Lead,** fairly steady, at £24. 7s. 6d. prompt, and £23. 17s. 6d. per ton forward, for foreign; English, £25. 15s. **Spelter** prices were firmer at £30. 2s. 6d. per ton, f.o.b. **Zinc Sheets,** active, at £38. 17s. 6d. per ton on rail at works. **Sulphate of Ammonia,** quiet, at £14. 15s. to £13. 12s. per ton. **Sulphate of Copper,** dull, at £26. 7s. 6d., less 5%, in casks, f.o.b. **Nitrate of Soda,** more active, at £13. 7s. 6d. per ton prompt, and £13. 12s. 6d. forward. **Bone Meal,** slow with prompt; Indian £8. 17s. 6d. per ton. **Sulphuric Acid** in steady demand, with fair supplies at £3. 7s. 6d. to £6. 17s. 6d. per ton. **Oxalic Acid,** very dull, at 6¼d. per lb., f.o.r. **Pitch** keeps very dear, with no signs of reductions in prices, which stand at £6. 12s. 6d. for inferior qualities. **Copperas,** rather dull, at £2. 2s. 6d. per ton. **Arsenic** still remains in scant demand, with white powdered at £70. per ton. **Raw Linseed Oil,** prompt, £2. 4s. 9d. per cwt., in barrels. **Cottonseed Oil,** common edible £2. 4s. 6d., and deodorised £2. 7s. 6d. **Cocoanut Oil,** slow, with Ceylon £2. 2s. 3d. per cwt., f.o.b. **Olive Oil,** little doing, with prompt £67. 2s. 6d. per ton. **Palm Oil,** quietly steady; Lagos, prompt, £34. 15s.; softs, prompt, £34. 2s. 6d.; mediums £34. 15s.; and hards £36. 2s. 6d. per ton. **Turpentine,** quiet with American, prompt, £3. 19s. 3d. per cwt. **Coals** were steady, with numerous inquiries for steam qualities; best Admiralty £1. 10s., seconds £1. 9s., ordinaries £1., Monmouthshire black vein £1. 8s. 6d., all per ton f.o.b. **Anthracite** coals were firm, with best large at £2 10s.; French nuts £3. 2s. 6d. per ton, f.o.b. **Patent Fuel,** prices were very steady, from £1, 12s. 6d. to £1. 15s. per ton, f.o.b.. **Cokes** were inclined to be firmer, more especially the better foundry grades, at £2.; furnace £1. 10s. per ton; export £2. 10s., f.o.b.

LIVERPOOL CHEMICAL MARKET. WEDNESDAY.

Inquiries for chemicals of the heavier kinds have again been moderate in number, as far as requirements for the home trade are concerned. In the export branch trade has been moderately active and shipments of chemicals are being made steadily and on a fair scale. **Bleaching Powder** has been rather more in demand, and is £10. to £11. per ton for use in the United Kingdom and £11. per ton for export. **Calcium Chloride** has been in fair request, and is £5. 17s. 6d. per ton. **Caustic Soda** has been in quietly steady demand on home-trade account, but has again had a moderate shipment for foreign ports; it is £20. 7s. 6d. to £21. 7s. 6d. per ton for 76%, carriage paid, for home-trade use, and £20. 10s. per ton for export. **Bicarbonate of Soda** continues to sell rather freely on home-trade account and has had a very firm shipment for export; it is £10. 10s. per ton, carriage paid, for use in the United Kingdom. **Soda Crystals** have had a fairly active inquiry, and are £5. 5s. per ton for home-trade uses. **Nitrate of Soda** has been but little in demand, and is £13. 5s. to £13. 10s. per ton. **Borax** has been in very fair request for use in the U.K., but has been quiet in the export trade; commercial crystals are £27. per ton, and powdered £28.; higher grades are, crystals £31. per ton, and powdered £32. per ton, carriage paid in the U.K. **Saltcake** has been quieter; it is £4. 10s. to £5. per ton for home-trade uses, and £5. 10s. to £6. per ton for export. **Bichromate of Soda** has had a slow sale, and is 4½d. per lb., c.i.f. to usual ports. **Ammonia Alkali** has been steadily called for on home-trade account and has been in good demand for export; the price is

£7. 12s. 6d. per ton for home-trade uses, and £8. per ton for export. **Hyposulphite of Soda** has been in very fair demand, and is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial, and £15. to £16. per ton, in 1cwt. kegs, for photographic. **Sulphide of Soda** has had a very limited inquiry; solid is £16. per ton, and crystals £10. 10s. to £11. per ton. **Chlorate of Soda** has been quiet, and is 3d. to 3½d. per lb. **Phosphate of Soda** has been very quiet, and is £15. to £15. 10s. per ton. **Prussiate of Soda** has moved but slowly, and is 7d. to 7½d. per lb. **Yellow Prussiate of Potash** has been in fair request and the price is slightly lower; it may be given as 1s. 3d. to 1s. 3½d. per lb. **Red Prussiate** has been quiet, and is 3s. 3d. to 3s. 6d. per lb. **Carbonate of Potash** has been but little in request, and is £26. to £32. per ton, according to quality. **Nitrate of Potash** has again been steadily inquired for, and is £33. to £35. per ton for refined. **Chlorate of Potash** has been but little called for, and is 4d. to 4½d. per lb. **Caustic Potash** has been quiet, and is £32. to £33. per ton. **Permanganate of Potash** has had a fair inquiry, and is 10d. to 10½d. per lb. **Bichromate of Potash** has been rather more in request, and is 5¾d. per lb., c.i.f. to usual ports. **Salammoniac** has had a moderate inquiry; first quality is £63. per ton, second quality £60., and third £57. **Sulphate of Ammonia** continues quiet for use in the U.K., but has moved somewhat freely in the export branch; neutral is £14. 15s. per ton, and ordinary £13. 12s. per ton, to the end of August. **Carbonate of Ammonia** has had a fair inquiry, and is 4d. per lb. **Muriate of Ammonia** has moved but slowly, and is £32. to £33. per ton. **Magnesia** has been in rather good demand; **Carbonate** is £2. 5s. per cwt., and **Sulphate** £5. to £6. per ton. **Alum** has been more inquired for; it is £12. per ton for the home trade and £11. 10s. to £12. per ton for export. **Sulphate of Alumina** has been in fair request, and is £8. to £12. per ton, according to quality. **Sulphur** has been in very fair demand; flowers are £10. per ton, roll is £8. 10s. per ton, rock is £8. to £8. 10s. per ton, and American £5. to £5. 10s. per ton. **Tartaric Acid** has been more in request, and is 1s. 3d. to 1s. 3½d. per lb. **Cream of Tartar** has been in good demand, and is £4. 12s. to £4. 15s. per cwt. **Boric Acid** has been in steady request. **Commercial Crystals** are £52. per ton and powdered £58., and £2. more per ton if in casks. **Citric Acid** has been well inquired for, and is 1s. 9d. to 1s. 10d. per lb. **Oxalic Acid** has been very quiet, and is 6¼d. to 6½d. per lb. **White Acetate of Lead** has been more in request, and is £42. to £43. per ton. **Sulphate of Copper** has been quiet for the home trade, but has had a fair shipment for foreign ports; it is £26. to £26. 5s. per ton, less 5%, in casks, f.o.b. at Liverpool. **Arsenic** continues quiet, with Cornish still in small supply; white powdered is £71. to £72. per ton.

WEST OF SCOTLAND CHEMICALS, Wednesday.

The demand for chemicals on home-trade account has been rather restricted on account of the holidays. Export inquiries also continue to be limited. Prices are easier in certain lines, but otherwise nominal quotations still hold steady. The following prices are at Glasgow, unless otherwise stated:—**Alum,** little doing, and in small demand; prices have been reduced and now stand at £12. 5s. for lump, and ground £12. per ton. **Arsenic** continues in short request, and supplies are still very scarce; it is quoted on spot at £76. 10s. net. **Barium Chloride** remains very quiet, despite a further reduction to £15. per ton. **Bleaching Powder** does not show much movement, and the quotation still stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax,** granulated, is on offer at £26. 10s. per ton net, in 2cwt. bags. **Calcium Chloride,** 70—75 per cent. solid, £5. 12s. 6d. per ton. **Citric Acid** is a declining market, though last week's reduced price is maintained at 1s. 8¼d. per lb., less 5%. **Copper Sulphate** is but little in request at last week's figure of £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar,** easier, with better inquiry, and the price is 2s. lower, at £4. 8s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in quieter demand; brown steady at £40. 10s. per ton, net, and white better at £40. 10s. per ton, net. The market for **Magnesium Chloride** is slow, with quiet business at £3. for spot. **Oxalic Acid** at 6¼d. per lb. **Paraffin Wax** experiences a fair export trade at 2¾d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull at the rather easier figure of 1s. 4d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1. 11s. per ton, but business is nominal. **Sodium Bichromate** remains steady, with business on the basis of 4¼d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2 cwt. bags; and £11. 10s. in 1 cwt. kegs. **Tartar Emetic,** 43—44%, in fair request at 1s. 1½d. **Tartaric Acid** still shows a quieter tendency at 1s. 2¾d. per lb.

IMPORTS OF CHEMICAL PRODUCTS

At the Principal Ports of the United Kingdom.

CHROME ALUM—
Christiania (F.), 4 kgs., £7.

CHROMIUM OXIDE—
Melbourne, 2 cks., £37.

CITRIC ACID—
Bermuda, 1 c., £5.; Bombay, 1 c., £11.; Calcutta, 7 c., £80.; Colombo, 2 c., £21.; Gothenburg, 6 c., £50.; Shanghai, 5 c., £54.; Stockholm, 5 c., £42.; Sydney, 1 c., £10.; Tokio, 1 c., £10.; Toronto, 1 c., £10.; Townsville, 2 c., £22.; Vancouver, 8 c., £67.

COAL TAR PRODUCTS—
Carbolic Acid
Alexandria, 20 drms., £25.
Colombo, 31 cs. (pt.), £6.
Creosote
San Francisco, 15 drms., £250.
Creosote Oil
East London, 50 drms., £7.
N. York, 777,751 galls., £28,700.
Naphthalene
Irish Free State (F.), 5 cs., £6.
New York, 1,000 bgs., £1,125.
Pitch
Calcutta, 20 brls., £55.
Rangoon, 20 kgs., £12.
Pyridine
Durban, 3 drms., £28.
Helsingborg, 7 drms., £341.
Tar
Sekondi, 10 brls., £24.
Sierra Leone, 25 drms., £7.

COPPER SALTS (*otherwise undes.*)
Melbourne, 1 cs., £23.

COPPER SULPHATE—
Durban, 4 c., £7.

CREAM OF TARTAR—
Hong Kong (F.), 2 c., £13.; Jaffa, 1 c., £7.; Lyttleton, 11 t. 8 c., £1,023.; Montreal (transit) (F.), 7 t. 10 c., £792.; Newcastle, 10 c., £53.; Pt. Elizabeth (F.), 11 c., £23.

CYANIDE OF LIME—
Rotterdam, 22 drms., £59.

DISINFECTANTS (*otherwise undes.*)
Accra, 9 c., £54.; Auckland, 4 c., £16.; Beira, 2 c., £11.; Bombay, 11 t. 3 c., £520.; Calcutta, 3 c., £27.; Colombo, 5 c., £21.; Irish Free State, 15 c., £51.; Kilindini, 5 t. 19 c., £214.; La Libertad, 18 c., £33.; La Union, 1 t. 10 c., £49.; Madeira, 4 c., £10.; Pt. Harcourt, 3 c., £11.; Pt. Sudan, 1 c., £5.; Walvis Bay, 1 c., £8.

DYESTUFFS (ARTIFICIAL)—
Alizarine
Bombay, 30 kgs., £172.
Unspecified
Adelaide, 1 cs., £14.; Aden, 1 cs., £8.; Auckland, 1 cs. (pt.), £24.; Barbados, 3 cs. (pt.), £13.; Calcutta, 9 cs., £43.; Dunedin, 1 cs. (pt.), £16.; Durban, 1 cs., £11.; Irish Free State (F.), 1 bx., £6.; Levuka, 5 cs., £61.; New York, 1 cs. (pt.), £8.; Penang, 1 cs., £18.; Perth, 1 ck., £9.; Pt. Elizabeth, 1 cs., £13.; Sydney, 1 cs. (pt.), £7.; Tokio, 1 cs., £75.

ETHER—
New York, 1 cs., £5.
Pt. Harcourt, 3 cs., £15.
Alexandria, 1 cs., £16.

FERTILISERS (*otherwise undes.*)—
Irish Free State (F.), 2 pkgs., £5.

FORMALDEHYDE—
Colombo (F.), 3 cs., £13.

GLYCERINE—
Amsterdam, 4 t. 14 c., £196.; Cape Town, 3 t. 2 c., £218.; Colombo, 1 c., £7.; Madras, 1 t. 19 c., £130.

GLYCEROPHOSPHORIC ACID—
Melbourne (F.), 1 cs. (pt.), £5.

HEXAMINE—
Melbourne (F.), 1 cs. (pt.), £5.

HYDROCHLORIC ACID—
Colombo, 5 c., £16.
Irish Free State, 2 c., £7.

HYDROCYANIC ACID—
Melbourne, 1 cs., £6.

HYDROGEN PEROXIDE—
Jaffa, 2 cs. (pt.), £5.

HYPOPHOSPHITES (*otherwise undescribed*)—
Boston, 68 cs., £1,023.

IODINE—
Adelaide, 1 cs., £53.
Perth, 1 cs. (pt.), £26.

IODINE (RESUBLIMED)—
Calcutta, 1 cs. (pt.), £27.

IRON AMMONIUM CITRATE—
Wellington, 1 cs., £11.

IRON CARBONATE—
Sydney, 1 ck., £12.

IRON SULPHATE—
Calcutta, 2 cs., £15.

LEAD ARSENATE—
Melbourne, 54 drms., £199.

LITHIUM CARBONATE—
Bombay, 1 cs. (pt.), £6.

LEAD CHROMATE—
Bordeaux, 5 cks., £35.

LEAD NITRATE—
Calcutta, 2 cks., £30.

MAGNESIA (CALCINED)—
Lisbon, 2 cs., £28.

MAGNESIUM CARBONATE—
Adelaide, 1 cs., £8.; Bombay, 6 cs., £26.; Melbourne, 45 cs., 11 pkgs., £112.; Mormugao, 3 cs., £7.; Sydney, 2 cs., £5.

MAGNESIUM SULPHATE—
Accra, 2 c., £6.; Bombay, 1 t., £28.; Cape Town, 13 c., £18.; Christchurch, 8 c., £11.; Jamaica, 14 c., £52.; Mormugao, 16 c., £21.; Toronto, 8 c., £19.

MANGANESE DIOXIDE—
Bangalore, 1 ck., £8.
Durban, 1 ck., £8.
Sydney, 72 pkgs. (pt.), £154.

MANGANESE HYDROXIDE—
Genoa, 2 cks., £15.

MERCURY IODIDE—
Melbourne, 1 cs. (pt.), £10.

NICKEL OXIDE—
Brussels, 1 cs. (pt.), £6.

NICKEL SALTS (*otherwise undes.*)—
Adelaide, 4 cs., £9.
Melbourne, 5 cs., £11.

NITRIC ACID—
Irish Free State, 5 c., £24.

PHOSPHORIC ACID—
Adelaide, 8 cs., £20.
Calcutta, 2 cs., £6.

PHOSPHORUS—
Melbourne, 1 cs., £9.

PICRIC ACID—
Sydney, 1 cs., £5.

PLATING SALTS (*otherwise undes.*)
Brussels, 2 cs., £35.

PLATINUM CHLORIDE—
Durban, 2 cs. (pt.), £10.

POTASH—
Melbourne, 2 c., £5.

POTASH (PEARL ASH)—
Melbourne (F.), 10 c., £15.

POTASSIUM BICARBONATE—
Callao, 1 ck., £6.

POTASSIUM BROMIDE—
Adelaide, 2 cs., £7.
Melbourne, 1 cs. (pt.), 10 cs., £43.

POTASSIUM CARBONATE—
Christiania (F.), 94 cks., £975.

POTASSIUM CHLORATE—
Irish Free State (F.), 1 kg., £6.

POTASSIUM CITRATE—
Adelaide, 1 ck., £12.
Melbourne, 1 cs. (pt.), 2 cs., £41.

POTASSIUM FERRICYANIDE—
East London, 1 cs. (pt.), £11.

POTASSIUM HYPOPHOSPHITE—
Sydney, 1 cs. (pt.), £7.

POTASSIUM IODIDE—
Accra, 2 cs., £38.
Bangkok, 1 cs., £92.
Calcutta, 1 cs. (pt.), £44.
Colombo, 31 cs. (pt.), £19.
Lome, 4 cs., £76.
Melbourne, 1 cs. (pt.), 1 cs., £135.

POTASSIUM PERMANGANATE—
Calcutta, 1 drm., £5.
Hobart (F.), 10 drms., £48.

POTASSIUM PHOSPHATE—
Sydney, 1 cs., £7.

POTASSIUM PRUSSIATE—
Melbourne, 2 cs., £15.

POTASSIUM SALTS (*otherwise undescribed*)—
Colombo, 31 cs. (pt.), £8.

PRUSSIAN BLUE—
Genoa, 8 cks., £344.

SALAMMONIAC—
Melbourne, 1 cs., £14.

SALICYLIC ACID—
Calcutta, 1 cs. (pt.), £6.; Melbourne, 1 cs., £13.; Shanghai, 1 cs., £7.; Singapore, 1 kg., £13.

SALTPETRE—
Adelaide, 2 t. 1 c., £87.; Durban, 1 t., £43.; Irish Free State, 3 t. 15 c., £156.; Lagos, 3 c., £10.; Melbourne, 10 t. 2 c., £416.; Perth, 1 t. 1 c., £43.

SILVER NITRATE—
East London, 1 cs. (pt.), £6.
New York, 1 cs. (pt.), £8.

SODA CRYSTALS—
Reval, 1 cs., £6.

SODIUM ARSENITE—
Delagoa Bay, 1 t., £72.

SODIUM BENZOATE—
Cape Town, 4 c., £45.

SODIUM BICARBONATE—
Fremantle, 6 c. £8.; Pt. Elizabeth 10 c., £15.; Toronto, 2 t., £100.

SODIUM CITRATE—
Melbourne, 1 cs., £5.

SODIUM GLYCEROPHOSPHATE—
Melbourne, 1 cs. (pt.), £6.

SODIUM HYPOPHOSPHITE—
Hong Kong, 1 t. 10 c., £30.
Melbourne, 1 cs., £15.

SODIUM IODIDE—
Melbourne, 1 cs. (pt.), £13.
Perth, 1 cs. (pt.), £6.

SODIUM PRUSSIATE—
Irish Free State, 5 t., £420.

SODIUM SALICYLATE—
Colombo, 31 cs. (pt.), £15.
Hankow (F.), 1 cs. (pt.), £8.
Melbourne, 1 cs., £14.

SODIUM SULPHATE—
Accra, 2 c., £7.
Barbados, 2 t. 15 c., £17.
Irish Free State, 2 t., £18.

SODIUM SULPHITE—
Durban, 1 t., £21.

SODIUM TARTRATE—
Adelaide, 10 c., £40.

SPENT OXIDE—
Hamburg, 1,208 t. 5 c., £2,033.

SULPHITE OF LIME—
Brussels, 2 kgs., £7.

SULPHUR—
Bagdad, 1 cs., £8.
Malacca (F.), 10 cs., £8.

SULPHUR (PRECIPITATE)—
Melbourne, 2 c., £8.

SULPHURIC ACID—
Accra, 3 c., £9.; Iddo, 1 t. 3 c., £44.; Irish Free State, 4 c., £14.; Memel, 2 t., £150.; Sekondi, 2 t. 9 c., £48.

TARTARIC ACID—
Calcutta, 4 c., £41.; Cristobal, 2 c., £12.; Colombo, 1 c., £8.; Gothenburg, 14 c., £90.; Hamburg, 1 t., £131.; Irish Free State (F.), 5 c., £35.; Irish Free State, 2 c., £14.; Lyttleton, 7 c., £47.; Mandalay, 1 c., £8.; New York, 2 t. 10 c., £327.; Penang, 1 c., £8.; Perth, 3 c., £28.; Shanghai, 5 c., £42.; Stockholm, 2 c., £13.; Townsville, 2 c., £16.; Viborg, 6 c., £41.

TANNIC ACID—
Shanghai, 2 brls., £9.

TIN OXIDE—
Brussels, 3 cs., 8 cks., £354.

ZINC OXIDE—
Amsterdam, 32 bgs., £95.; Malmo, 50 cks., £193.; Paris, 1 cs., £6.; Wellington, 11 bgs., £25.

Week ending July 21.

BEESWAX—

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	**19s. 6d.**	**24s.**
Half-yearly (26 numbers)	**10s. 6d.**	**13s.**
Quarterly (13 numbers)	**5s. 6d.**	**7s.**

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

The price of single copies is 6d. each, postage extra.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."

Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

THE VALUELESS GERMAN PATENT.

THE proceedings which the American Government are taking against the Chemical Foundation for the return of the patents purchased by the latter corporation from the Alien Property Custodian during the war are stretching out to an interminable length, and the end is not yet in sight. The latest plea put forward by the defence, however, is one that will be fully appreciated by those in this country who have had experience with German patents. American manufacturers who obtained licences from the Foundation to work the patents soon found that from an economic standpoint the documents were worth little more than the paper upon which they were printed, and that large sums had to be expended in detailed research before any of the processes could be placed upon a practicable basis. Dealing with the Haber nitrogen fixation patents, for example, Dr. Charles L. Parsons declared that in the 58 patents involved, and upon which the American Government place a value of 17 million dollars, the amount of really valuable information is practically nil. Similar evidence was given by manufacturers of dyestuffs and drugs under German patents. Thus vital steps were found to be omitted from the descriptions of the processes, and in those few cases where the methods could be followed the yields were low to the point of absurdity. This all confirms the view that to the German the patent was merely a legalised form of obstructing his competitors. Foreign patent laws had given him the opportunity of gaining a pronounced advantage over his rivals at a very small cost, and he was not slow to take advantage of the opportunity. It is the bounden duty of our chemists and lawyers to ensure that such an opportunity never again presents itself.

CHEMICAL-WASTE DUMP DANGERS.

THE death from sulphuretted-hydrogen poisoning, some weeks ago, of three men working in a pumping shaft and sump at a chemical waste heap near Bury, Lancashire, has focussed attention upon the potential sources of danger such heaps, which are scattered widely in various parts of the country, constitute. Our contemporary, *The Engineer*, which discusses the subject rather fully, expresses the view that the responsibility for taking precautionary measures when working near recent or old waste heaps should rest upon someone with

chemical qualifications, and that the engineer or contractor should be relieved of the responsibility. The fundamental soundness of this contention will be accepted by all chemists. The comparative freedom from serious mishaps that has hitherto characterised operations conducted in the neighbourhood of dumps is no argument for a policy of *laissez faire*. The close chemical supervision of all recent waste heaps will be comparatively simple to carry out, as such heaps are either on or adjoining the property of a chemical works. The position as regards old waste heaps which have been levelled, or have been covered over with layers of innocuous material, the existence of which may have been quite forgotten, is, however, not so simple. The only safe procedure would appear to be the compulsory registration of the site and extent of all chemical waste dumps with the district surveyor, who, in the event of the land being used at some subsequent period for building or other operations, would point out the danger, and make certain that adequate precautionary measures would be taken.

SERVICE CONTRACTS IN RESTRAINT OF TRADE.

The law relating to contracts made in restraint of trade, particularly as regards contracts of service, is of considerable interest to both employers of chemists and chemists themselves. Two weeks ago we printed part of an address given by Mr. E. J. MacGillivray, barrister-at-law, before the Institute of Chemistry, in which the opinion was expressed that the great majority of contracts now existing, containing a clause relating to restraint of trade, would, if challenged, be deemed unenforceable by the Court of Appeal or the House of Lords, even if the Court of first instance upheld the legality of the contract. A recent decision of the Court of Appeal (*H. J. Willett, Ltd., v. Beasley*) has proved the views held by Mr. MacGillivray to be correct. The particular case related to a contract between a firm of motor-car agents and their salesman, which contained a clause under which the latter had agreed that he would not, under penalties during five years after leaving the firm's service, be in any way engaged, or interested, in any branch of the motor business within a radius of fifty miles from the firm's headquarters. The appeal judges, in reversing the decision of Mr. Justice Roche in favour of the firm, who sought an injunction compelling the salesman to abide by the conditions of this clause, confirmed a recent judgment of Younger, L.J., in which he had held that the onus was upon the employer to show that the restriction imposed upon the employee went no further than was necessary for the protection of the employer's business. In the present case the Court held the restriction to be far too wide. The whole agreement was thus rendered invalid, and the injunction was refused Judgment was entered for the salesman. The important point is that within certain limits the law does permit restraints. In many cases it would be highly inimical to the interests of the chemical employer were he not able to impose reasonable restraints. So long as an employer does not impose upon his employee a restraint against fair competition and a restraint that is no wider than is reasonably necessary, there can be no legal objection. The greatest care and forethought are necessary, however, if the above two conditions are to be fulfilled.

COPPER PRICE PROSPECTS.

The publication by the United States Geological Survey Department of the corrected figures for the American copper production during 1922 has attracted considerable attention, and has led to the suggestion in several quarters that a rise in the selling price of the metal may be expected during the closing months of the present year. Practically the whole of the war-time stocks of old copper and brass scrap have now been disposed of, and supplies both for American domestic use and export must come out of current production. Stocks of refined copper at the end of 1922 were over 50 per cent. lower than twelve months previously. It is claimed by the American producers that statistically copper is better now than at any time since the armistice. Although the trade boom in the United States has passed its zenith, and the smelter copper production during 1922 exceeded that of 1921 by 200,000 tons, the fact that the price keeps up so well in America indicates that actual requirements are still being met with difficulty. Those who predict a higher price for the metal in the near future, however, base their prophecy largely on an early restoration of normal conditions in Europe, and the re-entry of Germany as a buyer, a view which the present political situation can scarcely be held to warrant. Still, the arguments that when a clearing up of the European political and industrial atmosphere does materialise, the price movement of copper will have an upward tendency, do not seem entirely devoid of validity.

GLASS IN FACTORY CONSTRUCTION.

It is generally believed that the extensive use of glass in the roofs and sides of factory buildings, whilst obviously of great value in giving a well-illuminated and cheerful interior, has in bright and hot weather the disadvantage of making working conditions inside the building extremely oppressive. Whilst this may be true for a factory in which the ventilation arrangements are not highly efficient, some interesting results that have just been made public demonstrate that when efficient natural ventilation is provided the disadvantage does not exist. The results in question were obtained in tests recently undertaken at the new engineering works of Messrs. The International Combustion Engineering Company, Limited, a works which has probably a greater glass area in the roof and sides per unit of effective floor area than any other factory building in the world. The tests have proved that during the recent heat wave the average temperature inside the shops when working at normal speed was actually lower by several degrees than that in the shade outside. There is nothing remarkable in the nature of the glass, but particular care was taken that means were provided for an effective and purely natural circulation of air.

THE ETHYL-ALCOHOL INDUSTRY.

A GENERAL SURVEY.

By "Omega."

ETHYL alcohol, in combination with various organic acids, occurs in a number of vegetable plants, and has been known since about the ninth century. Of the various alcohols a few have found industrial uses, but ethyl alcohol alone is of outstanding importance, has found the widest applications, is essentially a cheap commodity and should be treated as such. The Governments of the more prominent nations of the world have, during recent years, realised the vital necessity of the production and distribution of duty-reduced or duty-free alcohol when used for industrial purposes. Alcohol, besides being used for heating and power purposes, enters into the manufacture of nearly 200 industrial commodities. The statistics given below show the vast importance of alcohol in the explosives industry alone. The alcohol consumed in the manufacture of propellants during 1918 being:—

United States of America	52,500,000 gallons
France	33,600,000 ,,
England	16,000,000 ,,

The industrial use of ethyl alcohol has suffered no mean extent by the restrictions in its use and the safeguarding of the interests of the revenue authorities. Less serviceable substitutes have been used where pure alcohol would have given more efficient results.

Raw Materials for Alcohol Production.

The choice of raw material for use in the manufacture of alcohol is influenced more by economic than by chemical considerations. The range of materials which can be used is almost inexhaustible, an important fact in regard to its use as a motor fuel. The raw materials for alcohol manufacture fall into three main classes:—(1) Starch-containing materials—*e.g.*, potatoes, cereals; (2) Vegetation containing sugars—*e.g.*, sugar cane, beet, mangolds, fruits, and molasses; (3) Cellulose materials and residues. The table given below indicates how local conditions affect the choice of raw materials used. The figures are for the normal pre-war year 1913.

Material used.	Alcohol Produced (Gallons). Germany.	France.
Potatoes	66,000,000	—
Yeast	8,000,000	—
Grain	13,000,000	23,000,000
Molasses	3,000,000	12,000,000
Beet	—	42,000,000
Fruit	900,000	—

In England the principal raw material used in spirit manufacture is grain, maize constituting about 80 per cent. of the total used, other material used to a lesser extent being malt, oats, barley, rye, rice, and molasses. The chief source in America at the present time is cane or black strap molasses from the sugar refineries of Cuba, Porto Rico, and the South-Eastern States.

From a chemical standpoint almost any starch-containing material may be utilised as basis, but commercial and economic conditions operate to limit the availability of raw materials. During the war period, the Central European countries found potatoes easier to cultivate than cereals, and potatoes were used extensively as an alcohol source, beet-sugar molasses being used as a fertiliser. At the end of the war the number of potato distilleries in operation in Germany alone was 6,000 (*Zeit. Angew. Chem.*, Mar. 9, 1920). The table given below records the amount of alcohol obtainable from the various raw material:—

Material.	Fermentable Carbohydrates Per Cent.	Average Yield Per Acre. Tons.	Yield of Alcohol Per Acre. Gallons.
Wheat	66	0.5	42
Maize	68	0.7	61
Potatoes	18	7.0	139
Sugar Beet	16	15.0	298
Sorghum	15	16.0	190

Synthetically Produced Alcohol.

Synthetically, alcohol can be produced from its elements by electrolytic methods. The pioneer of synthetic alcohol was Hennell, who found in 1828 that by dilution and distillation of a concentrated solution of ethylene in sulphuric acid, alcohol was obtained according to the equations:—

$$C_2H_4 + H_2SO_4 = C_2H_5HSO_4.$$
$$C_2H_5HSO_4 + H_2O = C_2H_5OH + H_2SO_4.$$

The majority of the synthetic alcohol processes developed in war time used as a basis acetylene, which was in turn produced from synthetic calcium carbide. Processes in which the reduction of acetylene to ethylene has been effected have not attained any commercial success, it having been found to be more efficient to hydrate directly the acetylene into acetaldehyde using a mercury salt as a catalytic agent and then to reduce the acetaldehyde to alcohol by the Sabatier and Senderen reaction in which a mixture of the aldehyde vapour and hydrogen is passed over heated nickel at 140° C. Most of the earlier patents on the production of synthetic alcohol were based upon the initial reduction of acetylene to ethylene. Later Freeman (*Brit. Pat.* 28928, 1913), prepared pure ethylene by passing hydrogen under pressure—with the exclusion of air—between the carbon poles of an electric arc. The ethylene was absorbed in sulphuric acid and then converted into alcohol.

Under war conditions alcohol was produced synthetically to a large extent in Germany, but under the present economic conditions, reversion has been made to the fermentation methods. According to the Annual Report of the German Government Department on Alcohol for 1918, a firm at Lonza, Switzerland, offered to supply the Swiss Federal Government with rectified spirit at 1s. per gallon, but the Report considers it doubtful whether synthetic alcohol produced from calcium carbide will ever compete from an economic standpoint with that produced by means of fermentation processes. The opinion is expressed that the quantity of alcohol produced would be quadrupled by converting the carbide into cyanamide, and using the latter as a fertiliser for the potatoes to be used in the fermentation process.

Prospects for Synthetic Alcohol.

Detailed information concerning the production of synthetic alcohol in Germany is given in the schedules to the Spirit Monopoly Bill introduced into the Reichstag in August, 1921. The Expert Committee set up to investigate synthetic alcohol production, viewed with favour, synthesis from calcium carbide, a process which was then in operation at the Badische Anilin-und Sodafabrik Factories. According to *Chimie et Industrie*, November, 1921, during 1921, the estimated production of reparation dyestuffs alcohol was 90,000 gallons at the Ludwigshafen factory alone. The Bavarian works at Burghausen were anticipated to produce 220,000 gallons per annum. The total production of the ten alcohol factories in Germany producing spirit from sulphite liquor was: 730,000 gallons in 1920 and 1,200,000 gallons in 1921.

For the production of the basic material, the calcium carbide, England is not so well situated as countries which possess adequate water power. Prior to the war, calcium carbide was manufactured in Norwegian factories at £8. 5s. per ton, and that in a country with very limited lime and coal deposits. In studying the prospects of the production and utilisation of synthetic alcohol, the basic fact of fundamental importance is that the source of carbon in synthetic alcohol is coal, supplies of which are not inexhaustible, and will certainly become more difficult to obtain in course of time. The quantity of coal used in synthetic alcohol manufacture is necessarily high, owing, not only to that used in the carbide charge itself, but also in the production of the electrical energy utilised in the carbide manufacturing process. Some authorities claim that electrical energy may be obtained as cheaply near coal sources as near water-power stations. From a study of post-war problems, however, the synthetic alcohol question may reduce itself finally, not so much to the economic production of alcohol as to a conservation of coal supplies from a national asset standpoint. Recently, the production of economical electrical power in this country has engaged the attention of a committee of electrical engineers, who have suggested various schemes, the most important perhaps being the harnessing of the tides in the Severn, for establishing and controlling electrical distribution stations throughout the country. The materialisation of these schemes will have an important bearing on a large number of industries in this country, in effecting economies in coal consumption for power purposes, and diverting the supplies towards the production of synthetic products, of which alcohol is of paramount importance for chemical industries.

Pure and highly concentrated alcohol was first prepared in 1800 by Lowitz, who dehydrated the crude distilled product with potassium carbonate, and then distilled the alcohol in the presence of a further quantity of anhydrous potassium

carbonate. Drinkwater and Richter (*Crells Annallen* II. p. 221), used a mixture of hot calcium chloride and quicklime, and distilled at a low temperature. Squibb later applied distillation at a reduced pressure and obtained a highly pure product of specific gravity 0.7935 at 15.5° C. The modern method is to dehydrate by means of metallic calcium.

Commercial Production from Vegetable Products.

The commercial production of alcohol consists in the fermentation of cereals, potatoes or sugars. The first operation is either to hydrolyse certain plants or fruits, or allow carbohydrates to be acted upon by bacteria or moulds, thereby forming a wort, which is essentially the product of a diastatic fermentation process, maltose and dextrine being produced. The extract or wort is then subjected to alcohol fermentation induced by means of yeast. The weak alcoholic liquor is then submitted to fractional distillation, by means of which the alcohol is concentrated and isolated. The temperature of the wort fermentation needs considerable attention and skill, as otherwise excessive quantities of degradation products are formed. One of the features of alcohol manufacture is the quality and " age " of the yeast used. An impure yeast may introduce into the wort other ferments, with the production of acetic acid and acetaldehyde and consequent loss of alcohol. Wort fermentation difficulties are of more frequent occurrence during the summer months, possibly owing to the partial decomposition of the yeast during storage at a somewhat higher temperature. One of the operations in spirit manufacture requiring most skill is that of rectifying and distilling the weak alcoholic liquors. The type of still in general use in this country is Coffey's Distillation Apparatus, which combines the two processes of rectification and distillation, producing a comparatively pure product. The spirit obtained from this apparatus contains 94 to 96 per cent. by volume of alcohol.

Within recent years several attempts have been made towards the direct production of alcohol from cellulose. The latter material being converted into sugars by means of acid hydrolysis in autoclaves, and subsequently neutralised, fermented with yeast and distilled. During some experiments conducted in America using pine-wood saw-dust, the yield obtained was 175lb. of 95 per cent. alcohol per ton of wood used. In Norway, Sweden, and Switzerland, where cheap water power is available, alcohol is produced from the waste sulphite liquors obtained in the manufacture of wood and paper pulp. The alcohol content of these liquors is about 2 per cent., and is recovered by eliminating the sulphur dioxide, neutralising, fermenting, and distilling off the spirit.

Mariller and Ruymbeke (*Compt. Rend.* 175, p. 588 to 592), 1922, propose a method for the production of absolute alcohol at a low cost by the use of glycerine as a dehydrating agent.* It is claimed that a 99.9 per cent. alcohol, is obtained by allowing to run down the rectifying column a counter current flow of glycerine containing 30 per cent. potassium carbonate solution. The glycerine is recovered by heating under reduced pressure so as to eliminate the alcohol and water.

Denaturants and Excise Regulations.

Alcohol is met with under various names, generally indicative of an approximate concentration. Rectified spirit (*British Pharmacopœia*), requires a specific gravity of 0.8337 at 15/15° C., which is equivalent to 85.7 per cent. alcohol by weight. The U.S.A. Pharmacopœia requires a specific gravity of 0.820 which is equivalent to 91 per cent. Absolute alcohol as marketed contains up to 1 per cent. of water. Methylated spirit is duty-free alcohol, used in various manufacturing operations, and which has been denatured by means of certain solvents so as to render it unsuitable for potable purposes. The principal denaturants used are: wood naphtha, petroleum, and bone oil.

In England the Excise Authorities have authorised two varieties of methylated spirit:—(1) Industrial methylated spirit; its sale being restricted to particular manufacturing processes. This spirit contains a minimum of 5 per cent. denaturant, the type of which depends on the particular manufacturing operation to which the spirit is to be applied; (2) Mineralised methylated spirit; for general use (except as a beverage). It contains 10 per cent. wood naphtha and a small percentage of dyed mineral naphtha. Denaturants used in Continental countries are very similar, but slightly more varied so as to comply with the requirements of the various industries.

The Canadian Excise Authorities recognise 10 different grades of denatured spirit, and in the United States 81 are recognised. Amongst the denaturants used in America are pyridine, nitro-benzol, pine oil, iodine, cadmium iodide, ammonium iodide, brucine sulphate and diethylphthalate.

Particular concentrations of alcohol are used industrially, and may be prepared by diluting the quantities of 90 per cent. alcohol given below to one litre at 15° C.

	20 Per cent.	45 Per cent.	60 Per cent.	70 Per cent.
Sp. Gr.	0.9760	0.9435	0.9134	0.8899
Alcohol 90 per cent.	222.2 cc.	500 cc.	666.7 cc.	777.8 cc.

The following figures published by the Bureau of Internal Revenue U.S.A. for 1922, are of interest in view of the National Prohibition Act now in operation in America. At the close of the financial year 1922, it reports that there were, in operation: 73 industrial-alcohol manufacturing plants; 78 bonded warehouses; 74 denaturating plants qualified to operate for production, storage, and denaturation of alcohol, and that also, during 1922, the following new plants were established: 9 industrial-alcohol manufacturing plants; 10 bonded warehouses; and 12 denaturing plants. They collectively produced 80,000,000 proof gallons of alcohol. The number of licensed manufacturers using specially denatured alcohol at the end of 1922 was 3,287.

Physical Properties of Ethyl Alcohol.

The pure product is a colourless inflammable liquid, a powerful solvent, hygroscopic at high concentrations and miscible with water in all proportions. On mixing alcohol with water, contraction in volume takes place with evolution of heat. The physical constants of ethyl alcohol are as follows:—

Specific gravity 0/4° C.	0.8063
" " 15/15° C.	0.7936
" " 20/20° C.	0.7910
" " 25/4° C.	0.7851
Boiling point	78.4° C. at 760 mms. pressure.
Freezing point	−130.5° C.
Critical temperature	243.6° C. at 49 mms.
Flash point	12.8° C.
Spontaneous ignition in air	510° C. (Holm. *Zeit fur angew. Chem.*, 1913, xxvi., p. 273).
Explosive range	4–13.6 per cent. by volume (Lewes. *Jour. Royal Soc. of Arts*, 1915, p. 761).
Vapour pressure	43.8 mms. at 20° C.
Electrical conductivity	0.097×10^{-6} at 15° C.
Specific heat	0.6120 at 20° C.
Latent heat of evaporation	220.5 calories per gramme.
Refractive index	1.36332 at $n \frac{15°}{D}$
" "	1.35730 at $n \frac{30°}{D}$
Net calorific value	11,645 B.Th.U. per lb.
" " "	92,450 B.Th.U. per gallon.

Industrial Applications of Ethyl Alcohol.

Alcohol is used extensively as a solvent in the manufacture of chemicals and explosives, in the extraction of perfumes, essences and drugs, as a constituent of motor fuels and also as a preservative. In the dyestuffs industry, ethyl alcohol is used as a solvent, in the manufacture of ethers and of other intermediates. It is used for the extraction of turpentine gum and for the production of ethylene, which appears under various trade names for copper welding purposes. Strass (*Bestr. klin. Chim.*, 99, p. 402) states that ethyl alcohol is a powerful agent for tanning the skin, and hence localising the germs during surgical operations. Alcohol, alone or in admixture with ether or benzol, has been shown to possess superior qualities as a motor fuel, and is becoming an industrial rival to petrol. Although the calorific value of alcohol is considerably below that of petrol, its relatively greater combustion gives alcohol a higher efficiency. It has a high compression factor, and its property of high ignition temperatures under pressure is not seriously influenced by admixture with 20 per cent. of petrol or benzol, a mixture which starts an engine readily in the cold and gives smooth running. During the war much of the German military motor transport was run on high-alcohol-content fuel mixtures; and the experience gained at that period will lead probably to great developments in connection with the power alcohol question and resolve itself into a question of price. The miscibility of alcohol with water in all proportions offers also the use of alcohol a greater safety from fire compared with petrol. An Australian combine has been

* See also *Brit. Pats.*, Nos. 184,036 and 184,129, *Chemical Trade Journal and Chemical Engineer*, October 13, 1922, page 461.

formed recently on co-operative lines, to encourage farmers to raise sorghum crops, which are stated to yield over 80 gallons of 95 per cent. alcohol per ton of material. This project would render Australia independent of outside sources for liquid fuel, and Australian import duties paid on motor spirit last year were £2,500,000.

Alcohol as a Motor Fuel.

It will be some few years before pure alcohol will be used as a motor fuel, owing to mechanical difficulties and also Excise difficulties regarding denaturants, but it is already being used with advantage in America in admixture with other oils.* Its use is superior in that it burns more cleanly in internal-combustion engines, gives greater mileage, no pre-ignition, more power and more uniform application of power during piston power stroke. Owing to more complete combustion the efficiency is higher.

The British Inter-departmental Committee on the Production and Utilisation of Power Alcohol recommended as follows:—"As the price of alcohol for power and traction purposes to which we propose the name of 'Power Alcohol' should be given, must be such as to enable it to compete with gasoline, it is essential that all restrictions, concerning its manufacture, storage, transport, and distribution should be removed as far as possible, consistent with safeguarding the revenue and preventing improper use, and that cheap denaturing should be facilitated."

The intrinsic attraction of alcohol as an alternative for mineral oil fuels, is that its principal sources being the vegetable world, are almost inexhaustible and capable of much expansion without detriment to food supplies, whereas fuels obtained from coal or oil are necessarily limited in quantity and not inexhaustible, being confined to deposits limited in extent and which cannot be renewed. As the realisation of the advantages of the use of alcohol become more general, it will be used in greater quantities, but its future is entirely dependent upon its economical production.

SOCIETY OF GLASS TECHNOLOGY.

INTERESTING VISIT TO FRANCE.

IN connection with the visit of members of the Society of Glass Technology to France, during the first week of July, two meetings with French glass manufacturers were held on Monday, July 2nd. In the morning the visiting party was received by the Chambre Syndicale des Maitres Verreries, and was welcomed by its President, Mons. L. Houdaille, who described to the visitors how the French glass manufacturers were all united in one body—the Chambre Syndicale,—which was divided into six sections representing various branches of the industry. The work of these sections was organised in such a way as to prevent ruinous competition between members, and at the same time encouraged individual research and development. Mons. L. Delloye spoke of the need for co-operation among manufacturers of different countries Professor W. R. S. Turner, Colonel S. C. Halse, and Mr. E. A. Hailwood replied for the Society of Glass Technology.

List of Papers Communicated.

The following papers were communicated:—(1) Professor H. Le Chatelier, "La Méthode Scientifique dans L'Industrie"; (2) Dr. A. Granger, "Les Verres Opaques et Colorés, et les Glacures Céramiques de Même Espèce"; (3) Mons. Lafon, "La Dilatation des Verres et Cristaux"; (4) Professor W. E. S. Turner, "Specifications for Glass Products"; (5) Mr. T. Teisen, "Improvements in the Design of Recuperative Glass Pot Furnaces"; (6) Mr. S. English and Professor W. E. S. Turner, "The Physical Properties of Boric Oxide Glasses."

During the week visits were paid to the following glass works: (*a*) Etablissements Legras at St. Denis; (*b*) Verreries de Reims (Messrs. Charbonneaux and Cie); (*c*) New plate-glass works at Chantereine; (*d*) Glaceries de St. Gobain, Chauny, and Cirey. The social side of the excursion was not neglected. In addition to the reception and lunch already mentioned, a number of other receptions was given, and also a complimentary dinner by members of the visiting party to Mons. L. Delloye, who had been responsible for making all the arrangements on the French side.

* The new regulations whereby the use of 10 per cent. of ethyl alcohol in all imported fuels for internal-combustion engines has been rendered compulsory in France, has already been referred to in these columns on several occasions.—ED. *C.T.J. and C.E.*

THE ESTIMATION OF GLYCERINE.

NEW ITALIAN DIRECT METHOD.

IN a paper which was presented by Professor S. Fachini at the Italian Congress of Chemistry, held in Rome from June 3 to June 7 last, and to which reference was made in our issue of July 6, page 10, a detailed critical examination of the various methods proposed for the estimation of glycerine was made. The methods in question include the oxidation methods based on the use of permanganate of potash, proposed by Benedikt and Zsgimondi; the potassium bichromate and sulphuric acid method, proposed by Legler, Burkhardt, Cross, Bevan and Hehner, and by Plancon, Herbig and Suhr; the method based on the transformation of the glycerine into nitro-glycerine, proposed by Champion and Pellet and by Lewkowitsch; the triacetin method of Benedikt and Cantor; the iso-propyl iodide method of Zeisel and Fanto; the acrolein process of Ztzsche, and other methods based on the indirect determination of glycerol. The paper then mentioned a method of direct determination, proposed originally by Shukoff and Schestakoff, and modified by Fachini and Dorta, in which the glycerol is extracted with acetone and weighed.

Limitations of the Acetin and Bichromate Methods.

Of all the above methods, two only—namely, the acetine process and the bichromate process—enter into common use with the analyst, and these were retained as official methods by an International Committee in 1911. Unfortunately, these two methods do not give identical results, and even to-day there is felt the necessity of a single method that can unify and co-ordinate the results of the analysis of all glycerines.

Pure glycerines and crude glycerine do not only consist of pure glycerol $C_3H_5(OH)_3$ and water, but contain other constituents, amongst which tri-methylene-glycol $C_3H_6(OH)_2$ may be specially mentioned. From the theoretical point of view the acetin method of determining glycerine is more logical than the bichromate process, since in the former the alcoholic hydroxyl groups enter into the reaction. The glycerol content determined by the acetin process depends, therefore, on the content of hydroxyl group in the sample under test, and in accordance with this method the tri-methylene glycol, calculated as glycerol, corresponds to 80.69 per cent.

The bichromate process, on the other hand, oxidises both the glycerol and the tri-methylene-glycol, transforming these into carbonic acid and water. In this process, since the molecule of tri-methylene-glycol absorbs one atom of oxygen more than does the molecule of glycerol, it is evident that too-high results are obtained, and, in fact, the tri-methylene-glycol, calculated in this case as glycerol, corresponds to 138.3 per cent. It is clear, therefore, that neither of the above two methods can give the exact content of glycerol in a glycerine, but only very approximate results, the real content of glycerol and tri-methylene-glycol being obtained through the union of the two methods, or by the other method that will be described below.

Even if, theoretically speaking, the acetin method is more accurate than the bichromate process, yet it is so delicate that it is not possible to avoid errors. Above all, it is very difficult to neutralise the excess of acetic acid after the esterification, especially owing to the fact that the mass to be treated is always about five hundred cubic centimetres—a volume sufficiently great to require an excess of alkali to influence the indicator. The addition even of a very small excess of alkali means the saponification of a part of the triactin, leading to serious errors. For this reason attempts to eliminate the excess of acetic acid, by transforming it into acetanilide, and separating the triacetin from the mixture by organic solvents have been made, with but little success however. In addition, the great ease with which triacetin hydrolyses must not be overlooked. The acetin method is, moreover, extremely tedious and complicated, it being necessary to repeat each determination, with the concomitant dangers of error indicated above, not only on the glycerine, but also on the reagents and on the organic residue at 160° C.

For the above reasons, Professor Fachini thinks the bichromate of potash method the better of the two, when accuracy and speed are required, and especially if this method be carried out together with other determinations which permit, from the apparent or approximate content of glycerol

at first obtained, the real contents of glycerol and the contents of tri-methylene-glycol to be deduced with accuracy.

Measurement of the Carbon Dioxide Evolved.

If the calculation of the glycerol content is not based on the quantity of bichromate of potash reduced, but on the quantity of carbonic acid evolved during the oxidation, it is possible to obtain much more exact results. When considering separately the oxidation of glycerol and tri-methylene-glycol, the following equations are obtained: —

$$C_3H_5(OH)_3 + 7O = 3CO_2 + 4H_2O$$
$$C_3H_6(OH)_2 + 8O = 3CO_2 + 4H_2O$$

From these it is seen that 132 parts per weight of carbonic acid correspond to 92.064 parts of glycerol and to 76.064 parts of tri-methylene-glycol, and that if the tri-methylene-glycol be calculated as glycerol the result corresponds to 121.03 per cent., which means a great advantage over the usual bichromate process, where the tri-methylene-glycol, calculated as glycerol, corresponds to 138 per cent. The principal value of the new carbonic acid method consists, however, in the possibility of determining simultaneously the glycerol and tri-methylene-glycol. The equations given above show that the quantity of carbonic acid evolved during the oxidation of the glycerol and during the oxidation of the tri-methylene glycol is identical, and for this reason the quantity will be identical with a sample constituted entirely either of glycerol or of tri-methylene-glycol. The quantity of oxygen or bichromate of potash necessary for the oxidation will, however, be different, and the quantity of this required will be larger when the content of tri-methylene-glycol is higher.

When the quantity of carbonic acid evolved during the oxidation of a given quantity of glycerine has been determined, the approximate quantity of glycerol in it can be calculated at once, and will always be more accurate than when calculated on the amount of bichromate used.

To obtain the actual contents of glycerol and tri-methylene-glycol, the theoretical quantity of bichromate that would have been necessary for the oxidation of the sample if this was constituted only of glycerol is calculated from the carbonic acid produced, and compared with the quantity of bichromate of potash actually reduced. If the sample contains tri-methylene-glycol, the theoretical quantity of bichromate of potash will be smaller than that actually reduced, and the difference will represent the bichromate employed for the oxidation of the trimethylene-glycol. Knowing from the above two equations that every 16 parts of oxygen in excess correspond to 76.064 parts of trimethylene-glycol, or (that in this case one gramme of bichromate of potash equals 0.7748 of the glycol) it will be easy to determine exactly the quantity of the same. This, calculated as glycerol, is deducted from the approximate quantity of glycerol first found, and calculated on the carbonic acid produced. In this way the real glycerol present in the sample is found.

Deduction of the Quantities of Glycerol and Tri-methylene-glycol Present.

Taking a as the quantity of glycerine weighed as the sample under test, B as the quantity of bichromate actually reduced, B_1 as the theoretical quantity of bichromate calculated on the carbonic acid produced, G as the approximate quantity of glycerol calculated on the carbonic acid evolved, and C as the quantity of carbonic acid evolved during the oxidation.

1 gramme of carbonic acid = 0.57624 gramme of glycol.

1 gramme of carbonic acid = 0.69745 gramme of glycerol.

1 gramme of glycerol = 7.4564 grammes of bichromate of potash.

1 gramme of bichromate in excess = 0.7748 gramme of glycol.

X = amount of glycerol present.

y = amount of tri-methylene-glycol present.

It is seen that—

$$G = C \times 0.69745$$
$$B = G \times 7.4564$$
$$y = (B - B_1)\,0.7748$$
$$X = G - \frac{y \times 92.064}{76.064}.$$

Experimental Details of New Process.

Pure glycerines are submitted at once to oxidation. A thin glass flask of fifty cubic centimetres capacity is tared, 20 grammes of water are added, and then from four to five drops of the glycerine to be analysed. The whole is then weighed again. About 1.5 grammes of bichromate (1 gramme of glycerine = 0.4564 gramme of bichromate) are then added, and the whole weighed again.

The flask is then closed by a rubber stopper with three holes, through one of which is inserted a small tap funnel; through another a tube for the entrance of the air, reaching to the bottom of the flask; and through the third an exit tube for the air and carbonic acid. The exit tube is provided with a two-bulb tube and with a water condenser, so as to condense as much as possible the steam formed when the flask is warmed. The exit tube is also connected with a U-tube containing small glass beads moistened with concentrated sulphuric acid, and with three other U-tubes containing anhydrous calcium chloride, submitted before use to the action of carbonic acid, so as to eliminate any lime that may be present in the chloride.

The absorption apparatus for the carbonic acid—the usual combustion apparatus—is weighed, and is connected to the last U-tube mentioned above. To the absorption tube is then connected still another small weighed U-tube containing calcium chloride, to absorb any moisture escaping from the absorption apparatus; and this is followed by a final tube containing calcium chloride, to protect the one preceding it from atmospheric moisture.

When the flask has been connected to the apparatus described, the entry of the air is stopped, and about nine cubic centimetres of sulphuric acid of 66° Bé. are made to drop through the tap funnel. The acid is made to drop slowly, and not to have any loss of carbonic acid it is advisable to operate as follows. To the upper opening of the funnel there is a tap supplied with an indiarubber tube. By blowing gently down this tube with the mouth a small pressure on the acid is exerted, and the latter is thus made to drip out slowly, until the funnel contains a small residue of about one-half one cubic centimetre. This small pressure is necessary, since the carbonic acid that is at once evolved would otherwise escape through the funnel, and not through the exit tube. The small residue of acid must be left in the funnel, to avoid blowing directly carbonic acid with the mouth into the apparatus. After the above operation has been effected the analyst waits until the evolution of the carbonic acid has somewhat subsided, and then immerses the flask into a beaker of hot water, and maintains the latter in slow ebullition for about two hours.

At this temperature the glycerine is completely oxidised, whilst if there are traces of acetic acid in it they remain unaltered up to a temperature of 120° C. After the two hours' treatment, the tap leading in the air is slowly opened, and a gentle stream of air is caused to pass through the whole apparatus for about three-quarters of an hour, the warming of the flask being discontinued after one-quarter of an hour. In this way all the carbonic acid is collected in the absorption apparatus, which is then weighed together with the calcium-chloride tube which serves as a control.

The difference in weight gives the quantity (C) of carbonic acid evolved from the quantity (a) of glycerine. The contents of the flask are transferred quantitatively into a tared flask of five hundred cubic centimetres capacity, and made up with distilled water to the mark at 15° C. From the resulting solution fifty cubic centimetres are pipetted into a glass beaker, and 2 grammes of crystallised potassium iodide and 25 cubic centimetres of 20 per cent. hydrochloric acid are added, finally diluting with water to about one-half litre. The excess of bichromate is now titrated with decinormal thiosulphate of soda, using starch as indicator.

Accuracy of the New Method.

In this way there is obtained the weight (B) of bichromate actually reduced by the quantity (a) of glycerine, after which all the factors for proceeding with the calculations are available. The method was tested on several samples of chemically-pure glycerol, and the following results were obtained: —

	Old Bichromate Method. Per Cent.	Carbonic Acid Method. Per Cent.
Sample A	0.918 ...	0.916
Sample B	88.90 ...	88.69

THE FACTORY INSPECTOR'S REPORT.

INDUSTRIAL DISEASES IN 1922.

DR. T. M. LEGGE, H.M. Senior Medical Inspector of Factories, contributes as usual a chapter on industrial diseases in the Annual Report for 1922 of the Chief Inspector of Factories and Workshops, which has just been published (H.M. Stationery Office; price, 5s. net).

The Effects of the New Chemical Works Regulations.

It might perhaps be mentioned that the general report comments upon the new Chemical Works Regulations as follows: These Regulations, which did not come into force until October 1, 1922, supersede the old Special Rules for Chemical Works (made nearly 30 years ago), the Regulations for Nitro- and Amido- Derivatives of Benzene, those for Chromate and Bichromate of Potassium or Sodium, and embody the Voluntary Code for the Distillation of Tar. The difficulties met with so far in administration have been few and there is good reason to anticipate that compliance will be secured without serious difficulty. In a code of this character, dealing with a varied class of industry ranging from the manufacture of pharmaceutical preparations on the one hand to large alkali works on the other, the need for power of exemption, to meet the varying conditions under which the processes are carried on, is evident. Certificates of exemption have so far been granted in a few cases only, other claims, dealing more particularly with the manufacture of sulphate of ammonia and with the dehydration of tar in gas works, are at present under consideration.

Experiments are being made by the Chemical Warfare Committee of the War Office to determine what class of self-contained breathing apparatus can be sanctioned for use in gas contaminated atmospheres, such as occur in some chemical works, and the conditions under which their use can be allowed. Meanwhile no authority to use self-contained breathing apparatus has been sanctioned, and occupiers have been advised to rely upon a face mask provided with a tube passing to the outside air.

As the Regulations have been in operation for so short a period, it is not possible to give any detailed account of their observance. The preliminary reports which have been received, more particularly from Mr. Brothers (Warrington) in whose area a large proportion of the more important works are situated, are entirely satisfactory, and suggest that in many works a full measure of compliance has already been secured. Certain difficulties of interpretation are foreshadowed, as regards, for instance, whether there is or is not a "liability to explosion" in individual cases such as to necessitate the precautions against naked lights and fires required by Regulation 4, and whether or not dangerous gas or fume is "liable to escape" under particular circumstances, and so necessitate the provision of rescue apparatus required by Regulation 6. With past experience to serve as a guide, there should not be serious difficulty in meeting objections of this kind.

The Regulations contain important provisions, making it obligatory, before any person enters any place where there is reason to apprehend the presence of dangerous gas, for a responsible person, specially appointed for the purpose, personally to examine such place, and to certify in writing that it is isolated and sealed from every source of gas or fume, and is free from danger.

Industrial Processes and the Primary Respiratory Diseases.

Reverting to Dr. Legge's report, the Inspector states that during the year Dr. E. L. Middleton completed his inquiry into the grinding of metals and cleaning of castings. He made physical examinations of 1,153 workers employed in the grinding, glazing, finishing, etc., of edge tools, textile machinery components, needles and hackle-pins, and in the dressing of castings in the Midlands, Sheffield, Lancashire and Scotland. His main conclusions are that these industrial processes are associated with the occurrence of three primary respiratory diseases, namely, pulmonary fibrosis, bronchial catarrh, and bronchitis.

Below is the table of notifications under Section 73, 1901, arranged under slightly different headings in some industries from those that have appeared since 1899.

Disease and Industries.	Reported Cases.*										
			Average.								
	1922.	1921.	1918-1920.	1915-1917.	1912-1914.	1909-1911.	1906-1908.	1903-1905.	1902.	1901.	1900.

* The principal numbers relate to cases, the small figures to deaths. Fatal cases not reported in previous years are included as both cases and deaths.

Lead Poisoning.

A glance at the table shows how in the pottery industry not only is the number of deaths to cases out of all proportion to those in the other industries on the list, but also the difference shown in this respect in the pottery figures themselves since the Workmen's Compensation Act, 1906, came into force, which, rightly, grants compensation to relatives for deaths due to the sequelae, such as chronic Bright's disease. A signal service in the prevention of lead poisoning was rendered by Mr. C. A. Klein, chemist to the Brimsdown White Lead Company, who worked out a method of incorporating dry lead compounds in rubber and other materials, in such a way as entirely to free certain processes from danger, thereby exempting employers from the onerous task, under the Indiarubber Regulations, 1922, of providing locally applied exhaust ventilation, periodic medical examination, and other precautions. The method is capable of extension in other directions—*e.g.*, in the glass industry. In this industry red lead, sometimes to the extent of 25 per cent., is mixed with the other ingredients, and every year cases of lead poisoning arise from this cause. Mr. Klein has prepared a fritted lead of low solubility to take the place of the crude red lead. Dr. Bridge visited premises following on a case of lead poisoning for collecting finely divided metallic lead. Analysis of the sample in the Government Laboratory showed that it contained 14 per cent. of soluble lead—a matter of interest, demonstrating that metallic lead, if in sufficiently fine state of division, is soluble and may cause poisoning. Dr. Henry, from Manchester, has given considerable attention to the occurrence of lead poisoning

in the manufacture of paints and colours, the heading of yarn, scrap lead melting, electric accumulators, and the painting of safes.

Mercury and Phosphorus Poisoning.

Four of the six cases of mercurial poisoning were caused by the accidental mixing of mercury with lead borings which were being melted. They all resulted from only one day's work at the process. The two other cases (1 fatal) occurred in the making of thermometers. No case of phosphorus poisoning was reported. Under the heading toxic jaundice are included two cases of poisoning by T.N.T., one a slight case in the melting and filling of shells, and the other severe in the breaking down process, in which T.N.T. is boiled out of shells and accidentally splashed over on to the buckets used near the tanks; from these it was absorbed in handling.

Chrome and Epitheliomatous Ulceration.

Of chrome ulceration 42 cases were reported—10 in the manufacture and 32 in the use of bichromate of potassium or sodium. The duration of employment per case where use was in question averaged 11 years, and in manufacture 4 years. The production of cancer by specific forms of irritation was a subject somewhat fully discussed at the annual meeting of the British Medical Association in July,* and served to show how important are the figures now available from the notification of epitheliomatous ulceration from pitch, tar, mineral oil, and paraffin, in their bearing on the experimental work now being carried on by several observers in this and other countries. Notification of epitheliomatous ulceration has now been required since 1920, and the number of attacks so reported is as follows:—

	1920.	1921.	1922.	Total.
Pitch	32	24^{2}	23^{1}	79^{3}
Tar	10^{1}	8	4^{1}	22^{2}
Paraffin	3	—	5^{1}	8^{1}
Total	45^{1}	32^{2}	32^{3}	109^{6}

Industrial Dermatitis.

More and more time has to be given by Medical Inspectors to the investigation of complaints of dermatitis, as to which generally in the industries of the country knowledge is wanted. Dr. Bridge sends me a brief account of some of his inquiries: *Celluloid Substitutes.*—As these substitutes contain formaldehyde, irritation of the skin produced by them can be readily understood. The rash affected the forearms, and was characterised by a vesicular papular eruption. At one factory the amount of formaldehyde present in the debris from the polishing machines, was found to be 0.015 per cent. of the total weight. *Shellac Varnish.*—Two works were visited in connection with inflammation of the skin of the hands and forearms, due to the use of shellac varnish. Where septic infection had not supervened, the cases quickly cleared up when removed from the work. In one instance the varnish was examined for the presence of arsenic, with a negative result. Irritation is primarily produced by the effect of the alcohol on the skin, but in one individual was undoubtedly mainly due to the active steps taken to remove the varnish from the hands before washing. *Sugar Dermatitis.*—In two large sugar refineries where over 4,000 persons are employed, particulars of 12 cases which had occurred within the last five years were obtained. From the history of the cases, the site of the onset of the dermatitis would almost invariably appear to be between the fingers, and the workers I was able to interview all stated that it commenced as a dry scaly condition, spreading along the inside of the fingers, and then to the back of the hands. It subsequently becomes moist, though rarely assuming the appearance of a true eczema. The conversion of the sugar lodging on the skin into butyric or lactic acid by the sweat has been suggested as the cause of this form of dermatitis. Though it has been difficult to demonstrate any actual injury to the skin by the sugar particles, I think this action plays some part in the production of the dermatitis.

Dr. Henry investigated cases of dermatitis from teak wood, and found dermatitis in four workers coming in contact with "accelerene" (para-nitroso-di-methyl-anilin), an accelerator used in the vulcanisation of rubber. Other evidence of dermatitis he found from lubricating oil, from shellac, and from sesqui-sulphide of phosphorus.

* See *Chemical Trade Journal and Chemical Engineer*, Dec. 29, 1922 (p. 789).

Poisoning by Fumes and Gases.

Below is a comparative table of the number of cases of gassing reported as having entailed absence for one day:—

	1913.	1914.	1917.	1918.	1919.	1920.	1921.	1922.
Carbon monoxide	59^{7}	62^{9}	99^{18}	54^{13}	85^{12}	56^{9}	77^{14}	111^{14}
(*a*) Blast furnace	20^{3}	20^{6}	22^{6}	17^{3}	33^{6}	20^{5}	18^{2}	28^{4}
(*b*) Power	21	21	32^{8}	21^{3}	19^{1}	16	27^{3}	37^{7}
(*c*) Coal	9^{4}	7^{1}	20	10^{4}	10^{4}	9^{3}	19^{4}	32^{1}
(*d*) Other	9	14^{2}	25^{4}	6^{3}	23^{1}	11^{1}	14^{5}	14^{2}
Carbon dioxide	12^{1}	3^{1}	1	5^{5}	3^{1}	—	5^{4}	1
Sulphuretted hydrogen	8^{1}	22^{3}	11^{4}	7^{1}	3	13^{4}	3	12^{3}

Ammonia	3	4^{1}	4^{1}	6^{1}	8	—	9^{1}	8^{1}
Benzol, naphtha, anilin	6^{2}	4^{2}	4^{2}	7^{4}	9^{3}	12^{1}	10	25^{1}
Arseniuretted hydrogen	2	1^{1}	12^{3}	2	3	5^{3}	1^{1}	1
Tetrachlorethane	—	25^{4}	—	—	—	—	—	—
Other (ether, acetone nickel carbonyl, carbon bisulphide)	—	—	4	1	3	9	3	10^{1}

Comparison of one year with another presents difficulties, especially in the case of carbon monoxide, as an escape of gas may affect several persons at the same time, and markedly increase the number for one particular year. Of 28 cases, with 4 deaths, due to *blast furnace gas,* 8 occurred in charging the cupola, 8 (1 fatal) in repairing furnaces and flues, 6 (1 fatal) from cleaning flues without efficient disconnection, 4 from leakage from underground flues, brickworks, etc., and 2 (both fatal) from leakage from valves. Of the 37 cases, with 7 deaths, from producer and suction gas, 12, with 1 death, occurred in connection with the charging, stoking, etc., of the generating plant, and 1 from starting the suction gas engine; 18, with 5 deaths, from the escape from the exhaust pipe into workrooms, in one case affecting 12 persons.

Of the 32 cases, with 1 death of coal gas poisoning 4 (1 fatal), occurred in gas works, the remaining 28 from distribution in workrooms as the result of defective fittings and inadequately ventilated gas stoves. Thus, an escape from the gas rings under the glucose pans in a sweet factory penetrated through the ceiling, and affected 13 persons. Again, 7 cases were due probably to escape from a flueless gas radiator in an ill-ventilated workroom. Other cases of carbonic oxide poisoning include 4 at lime kilns; 5, with 1 death, from the use of coke fires for heating rivets.

Seven cases of sulphuretted hydrogen poisoning, with 2 deaths (1 a rescuer) occurred in cleaning tar stills or tanks, and 2 in cleaning the oxide of iron purifying chamber.

Of the 10 cases of chlorine poisoning, 6 occurred from the increasing use of cylinders of chlorine gas in the bleaching of flour. Dr. Bridge, with Mr. McNair, visited several of these plants. Fortunately the makers are alive to the danger and issue instructions when installing them. As in the case of refrigerating plants, as far as practicable they should be outside the workroom. As a general rule they are placed in a small compartment off the main room.

With regard to *nitro and amido derivatives of benzene,* of the 19 cases, 11 occurred in the manufacture, 4 in packing the products, 3 from aniline (1 through wearing defective gloves and 2 others from boiling over of the liquid).

Death from Nickel Carbonyl Poisoning.

Six cases of nickel carbonyl poisoning, with 1 death, were reported, the symptoms being shortness of breath and bronchitis, following on deposition of the nickel in a fine state of division over the immense area of the respiratory surface. The poisoning was due to a leak of nickel carbonyl which escaped through a joint of a blank which had been inserted to isolate a gas filter and volatiliser. The men were employed for about two hours on repairs to the filter, situated a few feet above the volatiliser. Every apparent precaution was taken at the works in question to prevent escape of gas, and no case of any importance had occurred for 19 years.

Dr. Bridge made an inquiry into the conditions of the stoves in which sulphur is used for the bleaching of hosiery, following on a request from the Superintending Inspector of the Eastern Division. Considerable discomfort is caused to the men who light the sulphur and who empty the stoves, but there is no doubt a large number of the men become acclimatised to the conditions of work. A conference with the manufacturers is being held in the early part of this year to consider the matter as a whole.

SAFEGUARDING OF INDUSTRIES ACT.

COMPLAINT AS TO ROCHELLE SALT UNDER PART I.

ON Tuesday, July 31, Mr. Cyril Atkinson, K.C., held an inquiry into a complaint that Rochelle salt has been improperly included in the Board of Trade List of dutiable articles under Part I. of the Act. The complainants were the Chemical Merchants and Users' National Vigilance Committee, which was represented by Mr. Kenneth Swan and Mr. R. Lambert Parry, the opponents being Messrs. Howard and Sons, Ltd. and Messrs. May and Baker, Ltd., represented by Sir Arthur Colefax, K.C., and Mr. Stafford Cripps. The Board of Trade also resisted the complaint, and were represented by Mr. Trevor Watson.

Point Should be Ruled by Tartaric Acid Decision.

Mr. Kenneth Swan, in stating the case for the complainants, said that a good deal was heard of Rochelle salt during the hearing of the cream of tartar and tartaric acid case, and if the case of Rochelle salt had been heard at the same time, there would have been very little difficulty in disposing of it on the same lines as the cream of tartar case. (The referee decided that cream of tartar, tartaric acid, and citric acid are heavy chemicals). In the case of Rochelle salt the Board of Trade contended that it was a fine chemical and also an analytical reagent. In order to show the close relationship between tartaric acid, cream of tartar and Rochelle salt, Counsel handed in the respective formulæ, adding that in the case of cream of tartar one of the hydrogen atoms in tartaric acid had been replaced by a potassium atom whilst in the case of Rochelle salt, the other hydrogen atom was replaced by a sodium atom. Rochelle salt appeared in the List of dutiable articles as such, as also as sodium potassium tartrate and potassium sodium tartrate and the application was to have all three struck out of the List, because they were three names for the same thing.

Uses of Rochelle Salt.

Counsel recalled that in the cream of tartar case two processes for the manufacture of that substance were mentioned, one, known as the St. Thibery process, in which argols was treated with calcium carbonate, and the other, known as the Rochelle-salt process, in which they proceeded, *via* Rochelle salt, to obtain tartaric acid and cream of tartar. In the latter case the argols was treated with sodium carbonate. The French people for the most part used the St. Thibery process, although there was one French factory where the Rochelle-salt process was used. In the cream of tartar case the English manufacturers pressed the point that their process was a fine chemical process *via* Rochelle salt, and one of the firms which used Rochelle salt as the intermediate or transitional body in the manufacture of cream of tartar was Messrs. Kemball, Bishop and Co., Ltd.

Apart from the use of Rochelle salt as an intermediate in the manufacture of cream of tartar and tartaric acid, the other uses of it were extremely small. It might be said that there was only one substantial use and that was in the preparation of health salts, such as Seidlitz powders and analogus products. Some years prior to the war, the importation of Rochelle salt into this country was restricted by agreement between the manufacturers here and the potential importers abroad, and for that reason he was not able to controvert the figures given by the Board of Trade as to imports. He would say, indeed, that the importation of Rochelle salt into this country was negligible under an agreement which might be temporary or permanent according to the will of the parties concerned. As to the reasons why the Board of Trade had included Rochelle salt as a fine chemical, the evidence would show that there was a very small amount of trade custom in this case, but in view of the close relationship between Rochelle salt and cream of tartar it seemed to him impossible to hold a different view from that expressed in the judgment in the cream of tartar case. He personally could not separate Rochelle salt from cream of tartar or tartaric acid. Indeed, he would go further and say it would be preposterous to hold that the intermediate product in the manufacture of cream of tartar —which latter had been decided to be a heavy chemical— was a fine chemical.

A Border-Line Case.

Counsel then proceeded to argue that Rochelle salt is one of the border-line cases, and contended that the onus was upon the Board of Trade to convince the referee that it should not be treated as a border-line case and given the benefit of the doubt. In this case there was no evidence, as far as he had been able to discover, that Rochelle salt had definitely been classified by the trade as a fine chemical, and in these circumstances he claimed that it could not be included in the Schedule as a fine chemical, and taxed.

The referee said he was not sure that that necessarily followed. He had been impressed very much by what Mr. Ballantyne had said in the calcium carbide case, that if it were found that a chemical had not been definitely classified, then one should look at the general attributes of fine chemicals and see whether the particular substance came within them.

Mr. Swan suggested that that would only apply in the case of a new chemical.

As to Rochelle salt being an analytical reagent, Mr. Swan said he placed it on the same basis as formaldehyde. None of the text books included it as an analytical reagent, nor did any of the catalogues, although it might be found so described in one or two encyclopœdic books. It was used, as the Board of Trade said, as an analytical reagent in Fehling's Solution, but Rochelle salt itself was not an analytical reagent.

Evidence of Mr. E. Parry.

Mr. E. Parry, who was the only witness called for the complainants, said he had not heard or seen Rochelle salt defined anywhere as a fine chemical. It was very rarely quoted in the trade reports, but it was more often than not referred to as a pharmaceutical chemical, if it was referred to at all. Witness was then taken through a number of catalogues and lists in none of which was Rochelle salt referred to as a fine chemical. These included Lists by R. W. Greeff and Co., Sparks, White and Co., lists of research and fine chemicals issued by the Association of British Chemical Manufacturers, and a list by Messrs. May and Baker. In all these cases Rochelle salt was classified under either general chemical or pharmaceutical chemicals. As a matter of fact, Rochelle salt was made by only one or two firms and did not come on to the market in the usual way. Therefore there were no market quotations for it. It almost invariably went from the manufacturers to the users, such as Eno's or Lamplough's or the wholesale druggists. In the case of the manufacture of cream of tartar, the Rochelle salt would not be separated. Of the quantity which was sold, 95 per cent. was used for the preparation of salines and health salts. According to the B.P., the purity must be not less than 98 per cent. Dealing with the use of Rochelle salt as an analytical reagent, Mr. Parry said it was a question of degree. He only knew of its use in this connection in two ways; either in Fehling's solution for the determination of sugar, or direct for the determination of quinine. Referring to the fine chemical point, witness said he had not been able to find a shred of evidence to support the Board of Trade contention that Rochelle salt is a fine chemical. It was handled by people who made and dealt in both fine and heavy chemicals.

The Analytical-Reagent Difficulty.

Cross-examining, Sir Arthur Colefax pointed out that in British Drug Houses, Ltd. List, citric acid and oxalic acid, which were not more used as analytical reagents than Rochelle salts, appeared, so that the lists did not carry matters very far. Mr. Parry admitted that he would not like to have to make up his mind whether Rochelle salt, used in a Fehling's solution, was an analytical reagent or not. He agreed that in Sutton's "Volumetric Reagents" there are 14 specific uses of Rochelle salt as a reagent, but 12 of them were never used, and substantially it was only used in the two ways he had pointed out.

After further discussion on these lines, the referee said he did not see how the complainants were going to get away from the fact that Rochelle salt is an analytical reagent. He asked Mr. Swan to speak to the point as to how it is possible to say that a substance used in a regular manner as an analytical reagent, as agreed by Mr. Parry, as Rochelle salt apparently was, should not be classified as such.

Mr. Swan said the matter was to be regarded from two points of view. In the first place Rochelle salt was used as an ingredient in a Fehling's solution and therefore, he contended, could not be said to be the reagent any more than the distilled water or other individual ingredients of the Fehling's solution. The other was that Rochelle salt was used to an extremely small extent by itself as a reagent in connection with the determination of quinine. If it were to be decided that because an infinitesimal portion of the output of a substance could be used as an analytical reagent

—the remainder having important commercial uses, for example,—then the whole of that substance was to be made dutiable, it would mean the inclusion in the List of a great many substances that were not now there. The words of the Act did not say "substances that can be used as analytical reagents" but "analytical reagents."

The Case Against the Complaint.

Sir Arthur Colefax, K.C., in opening his case for the opposition to the complaint, said that Rochelle salt was made by two firms in this country and curiously enough these two firms did not make cream of tartar, whilst the firms who made cream of tartar did not make Rochelle salt. His case was that Rochelle salt was a fine chemical because it was made in this country by firms who were essentially fine chemical manufacturers. Moreover, 95 per cent. of the Rochelle salt made here was used for pharmaceutical purposes and as such had to be of an extremely high degree of purity. With regard to the point as to Rochelle salt being an analytical reagent, his contention was that the quantity used for this purpose was immaterial for the purpose of the Act. In the B.P., Rochelle salt was listed as a reagent and it could not be said that because it was used in a Fehling's solution as one ingredient of that solution, it was any the less an analytical reagent.

The referee: I quite frankly agree that I think it is an analytical reagent.

Mr. Trevor Watson, for the Board of Trade, contended that from the mere fact that it had been admitted that Rochelle salt is an analytical reagent with a definite use——as stated by Mr. Parry—then the purposes of the Act were fulfilled and Rochelle salt was rightly included as an analytical reagent. It was not necessary for the referee to inquire whether a substance had any other use than that of a chemical reagent.

Mr. Swan replied that if the proposition just propounded were true and sound, then tartaric acid and cream of tartar, which it had been decided were heavy chemicals, would have to be included in the list as analytical reagents because they could be used for this purpose, and thus all the cream of tartar and tartaric acid coming into the country would have to be taxed. It was clear that consideration must be given to the other uses of a substance in deciding whether it should or should not be included as an analytical reagent.

Evidence from Messrs. Howard and Sons.

Mr. David Lloyd Howard, managing director of Messrs. Howard and Sons, Ltd., said he had been acquainted with the manufacture and sale of Rochelle salt for many years, and confirmed the statement already made by Sir Arthur Colefax that it is known in the trade as a fine chemical. The manufacture of Rochelle salt in this country was in the hands of four or five firms only who sold direct to the users and not through merchants. In order to obtain the degree of purity laid down in the B.P., it was necessary to have skilled supervision at every stage. The actual purity would be higher than the 98 per cent. laid down in the B.P., because the remaining 2 per cent. would be largely moisture. The high degree of purity coupled with the large use of Rochelle salt in pharmacy made it, in his opinion, a fine chemical. It was also a well known analytical reagent.

In cross-examination, witness said that from time to time some Rochelle salt came into this country from the Continent, chiefly Germany, but generally the home production was sufficient for our purposes, the consumption here being about 500 tons per annum. His firm never made cream of tartar and gave up making tartaric acid some years ago. Asked why, if the degree of purity of cream of tartar and Rochelle salt is practically the same, they both should not be fine chemicals—cream of tartar having been held to be a heavy chemical, witness said he did not manufacture cream of tartar and could not give an answer. Sir Arthur Colefax suggested that the B.P. requirements for cream of tartar are far less stringent than for Rochelle salt.

Certain references in the literature were then put to witness by Mr. Swan in further cross-examination, and the question was asked why, if Rochelle salt was a well known reagent, it was not included as such in the literature. The reply was that the catalogues and lists were compiled with great looseness, and, especially in regard to the book "Where to Buy Everything Chemical." Witness pointed out that in the case of sodium potassium tartrate, two of the largest manufacturing firms had been omitted from the list of such manufacturers. Moreover, sodium potassium tartrate was classified under "General Chemicals" in this book and was wrongly so classified, in his opinion.

Answering further questions on the fine chemical point, Mr. Howard said that he employed qualified chemists to do the analytical work, and the works directors, who were also qualified men, supervised the works processes. Four or five fully qualified chemists were employed; there were four trained chemists on the Board and there were also junior chemists employed in the works.

Further Trade Evidence.

Mr. P. Blenkinsop, director of Messrs. May and Baker, Ltd., manufacturers of Rochelle salt confirmed the previous evidence, and added that he did not consider cream of tartar a fine chemical on account of its large industrial use. Moreover, cream of tartar and Rochelle salt were handled by entirely different sections of the trade. The present price of Rochelle salt was £80. per ton. In his works about one-third of the time of a skilled chemist would be devoted to the work of supervising the manufacturing processes in connection with Rochelle salt, and the salary of the chemist in question was about £500. per annum.

Mr. Edmund White, managing director of Messrs. Hopkin and Williams, Ltd., the fine chemical branch of Messrs. Howard, said that Rochelle salt would be found in use in some form as an analytical reagent in every chemical laboratory for educational work and also for general analytical work. He also considered Rochelle salt a fine chemical, for the reason that it was produced under careful control and skilled supervision and with a high degree of purity.

The referee said a point which was worrying him was where they had a chemical which had an enormous industrial use and also some use as an analytical reagent of a very definite nature. He was wondering whether that had been contemplated by the framers of the Act. Sir Arthur Colefax said he could not think of a substance which would fall within this suggestion. Mr. Trevor Watson (for the Board of Trade) suggested that this was not the case here.

Conclusion of the Hearing.

Mr. Swan then briefly replied on the whole case. He had previously put his point with regard to Rochelle salt being an analytical reagent, and on the question of it being a fine chemical he pointed to the absence of any reference by the other side to the literature in which Rochelle salt was so described. The onus was on the Board of Trade to satisfy the referee that Rochelle salt is a fine chemical and was properly included in the List as such. The Board had failed to discharge that onus, and he claimed that he had succeeded on the point that Rochelle salt had been improperly included in the List as a fine chemical.

The referee's decision will be given in due course.

INDIAN MARKET FOR BRITISH HEAVY CHEMICALS.

THE United Kingdom supplies over two-thirds of India's chemical requirements, but Germany's share in the total trade has shown a striking increase and may offer strong competition in the future. Official statistics covering the fiscal year 1921-22 show that the total value of chemicals imported into India declined from Rs. 2,66 lakhs in 1920-21 to Rs. 1,91 lakhs, due to smaller quantities as well as lower values. Imports of sodium carbonate decreased slightly from Rs. 41 lakhs to Rs. 39 lakhs, of bleaching powder from Rs. 36¼ lakhs to Rs. 15½ lakhs, partly owing to increased local production, and of sulphuric acid from Rs. 2¾ lakhs to Rs. 1½ lakhs. The imports of all acids fell from Rs. 14½ lakhs to Rs. 5¾ lakhs. Alum was imported to the extent of Rs. 7 lakhs, and aluminous sulphates Rs. 4½ lakhs, half the value of the previous year. Magnesium chloride was imported to the value of nearly Rs. 4½ lakhs, as compared with Rs. 8¼ lakhs in 1920-21. Potassium compounds decreased from Rs. 7½ lakhs to Rs. 6 lakhs. Other prominent imports included caustic soda Rs. 13 lakhs (Rs. 16½ lakhs), sodium bicarbonate Rs. 11 lakhs (Rs. 7½ lakhs), and sodium bichromate, which remained stationary at Rs. 8 lakhs. Chloride of zinc decreased slightly from Rs. 5½ lakhs to Rs. 5 lakhs. Total imports of sulphur fell from Rs. 22½ to Rs. 11 lakhs, and marked a further decrease in Japan's share of this trade which amounted to only 1 per cent. or 90 tons. The chief sources of supply were the United States (2,900 tons), Italy (1,900 tons), and the United Kingdom (620 tons). The United Kingdom's share of the total trade in chemicals during 1921-22 was 71.4 per cent., as compared with 75.6 per per cent. in the previous year.—*Chamber of Commerce Journal.*

BRITISH ASSOCIATION OF CHEMISTS.

"Take my advice. Unite! Hold high the standard of chemistry and chemical industry."—Lord Moulton.

Hon. General Secretary: Mr. I. Boodson, Bedford House, 108, Baker Street, London, W. 1.
Hon. Registrar: Dr. David Bain, The Woodlands, Crescent Road, Crumpsall, Manchester.
Hon. Treasurer: Mr. H. E. J. Cory, Bedford House, 108, Baker Street, London, W. 1.
Hon. Editor: Mr. R. Brightman, 69, Devonshire Street, Higher Broughton, Manchester.

NOTICES.

Full information regarding the Association may be had on application to the Hon. General Secretary, to whom all applications for membership should be sent.

It is particularly requested that all changes of address be notified promptly to the Hon. General Secretary.

A register of members seeking appointments is kept at the registered offices of the Association. All inquiries should be addressed to the Hon. General Secretary.

Short articles, letters, etc., on matters of general interest are invited from members of the Association. These, together with all reports of meetings, should be sent to the Hon. Editor.

The annual general meeting of the Association will be held at Birmingham on Saturday, October 27, 1923.

PROCEEDINGS OF THE ASSOCIATION.

THE COUNCIL.

The Council met in London on March 17, and in Manchester on May 12 and July 7.

Unemployment Benefit Committee.—The Special Purposes Committee, in a report submitted to the January Council meeting, recommended that members compulsorily insured under the Unemployment Act should be exempted from the Fund so long as they were subject to the provisions of the Act. This, and a further recommendation that members on University staffs, or holding similar appointments, contributing to superannuation funds, should not be exempted from the Association's Fund, were adopted by the Council. The Council also decided that it was impossible to grant exemption to members compulsorily subscribing to Work's Benefit Funds. At the following Council meeting a case was brought before the Council of a member who, having paid six months' subscription to the Fund in advance, had become unemployed in the second month. The committee had decided that the member according to the rules was ineligibile to contribute while unemployed, and consequently was not eligible for benefit until he had been contributing as a member in employment for a further four months.

The report submitted to the July Council meeting by the Special Purposes Committee marked the end of the first year's working of the Fund, but, owing to the fact that during the first seven months nucleus funds were being accumulated and no benefits paid, the actual figures cannot be taken as representing a normal year's working. The data available, however, are of value in forming a more accurate estimate of the probable working of the Fund during the next year or so. They show the Fund to be financially sound and justify the optimistic forecast of its originators.

Subscriptions received during the year amount to £1,399. 3s., and benefits paid to £388. 2s. 6d. Administrative charges, including printing, postages, stationery, etc., amount to £30. 18s., and an additional amount of £101. 10s., being apportionment of rent and salaries is payable to the General Funds of the Association during the present quarter. The working expenses thus amount to less than 10 per cent. of the subscriptions received. The balance standing to the credit of the current account at June 30, subject to the apportionment charge already mentioned and to an amount of £89. payable for benefits accrued, is £492. 4s. 9d., £750. of 3½ per cent. Conversion Loan having been purchased at a cost of £608. 10s. 9d. Individual benefits paid during the past six months range from £4. to £95., the former representing 4 weeks at one unit, the latter 19 weeks at 5 units. That members appreciate the help given by the Fund is shown by the following letter recently received, which involves a voluntary foregoing of six weeks benefit:—"I start work in my new appointment on July 1. As this will naturally improve my financial position, and as I desire to show my appreciation of the help that the B.A.C. Unemployment Benefit Fund has been to me during the past few months, will you kindly consider that no further benefits are payable?"

Organisation of Research Associations.—The question of the organisation of various Research Associations, particularly in regard to the Government Grants and the benefit accruing directly to the public was brought before the Council by several of the local sections. Dissatisfaction with the Councils of certain existing Research Associations was freely expressed. On these Councils the chemists or other scientific workers directing the researches had no representation and very unsatisfactory programmes of research had been drawn up. It was agreed to request the local section committees to obtain further definite information concerning the activities of these Associations with a view to taking suitable action in co-operation with other bodies.

N.U.Sc.W. Negotiations.—Two further joint Council meetings with the N.U.Sc.W. have been held, and in connection with these negotiations the following members have been nominated to serve on joint committees:—Joint Publications Committee: Messrs. W. E. Kay, R. Brightman, E. H. Rodd. Joint Financial Proposals Committee: Messrs. H. E. J. Cory, S. R. Price and E. R. Redgrove.

Appointments and Resignations.—At the January Council meeting Mr. S. R. Price was obliged by pressure of other work to tender his resignation as Hon. General Secretary of the Association, but agreed to hold office until the next Council meeting. The Council accepted this resignation with deep regret. At the March meeting Mr. I. Boodson was unanimously appointed Hon. General Secretary to serve until the next annual general meeting. The Council has also received with regret the resignation of Mr. R. Brightman as Hon. Editor of the Association as from the end of the present year.

Other Business.—Considerable time was devoted to the consideration of the work of the Association during the ensuing year. It was agreed that a propaganda campaign should be inaugurated, working by means of special literature, an advertisement campaign in the Press and a series of rallies in the local sections, to be addressed by the Officers of the Association. It was further decided that consuls should be appointed to districts in which the Association is not already represented.

The attention of the Council was directed to two cases in which very inadequate salaries had been offered to chemists applying for posts, one being with a Corporation Gas Department and the other with a large electrical company. In the latter case a salary of £4. a week was offered for a man with at least two or three years work's experience and a thorough knowledge of both organic and inorganic chemistry. The letter addressed to the Association suggested that the chemist should also have had three or four years experience with a consultant analyst. The General Secretary replied stating that in view of the very low salary offered, he was unable to recommend any member of the Association to apply, and pointed out that a chemist with the qualifications desired was entitled to a commencing salary of at least £350. per annum.

MANCHESTER SECTION.

The annual general meeting of the section was held on March 28. In the course of his address the chairman, Dr. J. L. Hankey, referred to the activities of the section in connection with the Manchester Chamber of Commerce, on which the Association is represented by Mr. W. E. Kay and Mr. C. W. Carpenter. When the Chamber had arranged for its members to place before the local members of Parliament their views with respect to the Safeguarding of Industries Act and the Dyestuffs Act from the point of view of the manufacturer, the consumer and the merchant, our representatives had endeavoured unsuccessfully to obtain representation for the professional chemists engaged in those industries. However, it is realised that such efforts are of indirect value in bringing the Association before the notice of various important interests. After reviewing the activities of the Assocation such as the Appointments Bureau, the Legal Aid Fund, and the Unemployment Benefit Fund, Dr. Hankey discussed the question of the legal re-definition of the term "chemist." This he thought was a task that would require years for its fulfilment, but none the less he regarded the ambiguity at present attached to the designation "chemist" as one of the greatest hindrances towards a full recognition by the public of the proper status and dignity of the chemical profession. To the general public a chemist was still a man who sold or dispensed medicines, and the confusion was not removed by advertisements such as that recently inserted by the Retail Pharmacists' Associa-

tion in many important newspapers under the title "The Chemist." One well-known paper, commenting on a letter from the President of the Institute of Chemistry, expressed the opinion that it did not matter and that the context always told whether a scientist or an apothecary was meant. That was not the case and chemists desired that the word chemist should have one definite meaning and a similar professional implication in the public estimation to the words doctor, barrister, or solicitor. Only thus would the profession of chemistry secure the recognition to which it is entitled whether in industry, the Civil Service, or among the general public.

Dr. Hankey described the progress of the negotiations with the National Union of Scientific Workers, and explained the ideas underlying the joint activities contemplated. Chemists, he said, are scientific workers and all scientific workers have many common but comparatively few divergent interests. The various classes of scientific workers will of course have their own sectional interests, but these are seldom antagonistic and one might fairly say that on the whole all scientists were able to support whole-heartedly the economic and professional aspirations of their colleagues in whatever branch their work might be. Apart from this the N.U.Sc.W. included in their ranks a considerable number of chemists, who were for the most part engaged in Government service or in teaching whereas the majority of the members of the B.A.C. held appointments in industry. It was obvious therefore that if chemists were pressing for legislative or other measures in the House of Commons or elsewhere their case would be greatly strengthened if they could obtain for it the combined support of the two bodies. Advantages of this kind could not be obtained without a certain loss of independence, but in his judgment the advantages were well worth the price. However closely we might work with the N.U.Sc.W. we should retain for ourselves a sufficient measure of autonomy and the right to the distinct formulation of a programme. But without some kind of working arrangement Dr. Hankey was convinced that neither Association had any future.

In concluding, he urged that any society was what its members made it. In proportion as the members actively participated in its affairs by putting forward fresh ideas, making suggestions for the more efficient working of the society, supporting its journal by writing articles or by letters on matters of interest and by propaganda work among acquaintances so would that society be a growing and an influential concern.

LONDON SECTION.

The fifth annual general meeting of the London Section was held on Friday, April 6, at the Registered Offices of the Association, Mr. E. R. Redgrove in the chair.

After the usual business had been transacted, a general discussion on the work of the Association took place, the "B" qualification as usual being to the fore. An interesting paper on "Chemical Inspection" was then read by Mr. H. T. F. Rhodes, but the lateness of the hour prevented any discussion of the many points raised in the paper. Votes of thanks to Mr. Rhodes and to the Chairman and Officers closed the proceedings.

A very successful meeting was held by this section on June 1, in the Main Chemical Laboratory of the Royal College of Science, by kind invitation of the members of the Chemical Society of the Royal College of Science.

The speakers were to be Professor J. W. Hinchley and Mr. C. S. Garland, M.P. The former, unfortunately, was unable to appear, as he was called to Liverpool on an urgent legal case, but the latter rose to the occasion and fully justified his reputation as one of our best speakers.

His subject was "The B.A.C., what it is, what it can do, and what it cannot do." He gave a very succinct resumé of the activities of the Association, describing the work of the Unemployment Fund, the Legal Aid Department for advice upon such matters as Agreements, Victimisation, etc. He then dealt with the differences between the B.A.C. and Institute of Chemistry. Neither the Association nor the Institute were antagonistic to one another, but each had its own definite policy. Harmonious working was aimed at, and each was friendly toward the other. In its economic policy the B.A.C. was more free than the Institute, which was fettered by its Charter, while on the other hand the Institute as an examining body exercised greater influence in educational matters. It behoved every chemist to belong to both bodies if possible, so that he might partake of the full privileges of the profession. The B.A.C., of which he was one of the founders, was out to help the chemist in every direction. It was not a qualifying body and had never aimed at being such, but it was a body which had at heart the economic interests of chemists, the raising of the status of the chemist and of the plane of the profession of chemistry.

At the close of Mr. Garland's address an animated and interesting discussion arose, and a large number of the audience asked questions, indicating the great interest aroused by the address. These were adequately dealt with by Mr. Garland, and, after a cordial vote of thanks, the Chairman, Dr. H. F. Harwood, in the course of a few well chosen remarks, stated how glad he was to have been at the meeting and to have heard the elucidation of some obscure points. He was positive that everyone present had obtained a deeper insight into, and a clearer understanding of, the working of the Association and of the advantages enjoyed by its members.

THE MONTH IN ENGINEERING.

[Specially Contributed.]

The Recent Fuel Economy Congress in Paris.—There has been held in Paris, from June 8—17 last, an important Congress on "Fuel Economy and Industrial Heating," under the active Presidency of M. Walckaener, and the honorary Presidency of M. Le Chatelier. The proceedings included the reading and discussion of over 60 papers, which it is understood will be printed in one large volume (in French), which will be obtainable from the Secretary of the Congress du Chauffage Industriel, 246 Boulevard St. Germain, Paris. There was also held at the same time, from June 1—17, an exhibition of plant, machinery, and appliances relating to the business of the Congress. One of the chief features of the Congress was the attention devoted to pulverised fuel, and France is at present certainly doing more in this direction than any other country in Europe. It appears that the percentage of ash in most French coals is somewhat above the average, and as this may present some difficulties, several papers dealt with this aspect. It does not seem to have been quite realised, however, that the problem of the melting of the ash in the bottom of the furnace—that is, slagging—has now been entirely solved in America by the perfection of the water screen, combined with hollow air-cooled furnace settings throughout. A considerable amount of attention was given also to liquid fuel, in spite of the fact that this important question was discussed at great length at the International Conference on Liquid Fuels held in Paris last year.

The British contributions to the proceedings were represented by papers from Dr. C. H. Lander, who dealt with the work of the British Fuel Research Board, Dr. Marie C. Stopes, in connection with her well-known work on the constitution of coal, Professor Wheeler on his new method for determining in the laboratory the chemical re-activity of coke, and Mr. David Brownlie on the results being obtained on steam boiler plants in Great Britain, a suggestion for a new International Boiler Testing Code, and a third paper on the progress of low-temperature carbonisation throughout the world. The question of efficient steam generation in fact occupied a considerable amount of attention, another paper in this connection being that by M. Smal of Liege, who described in detail the work that is being undertaken in this direction in Belgium.

Research Professorships in Engineering.—The Royal Society have decided to establish in Great Britain a number of Research Professorships in engineering, that is to say, high grade posts in which the duties of the occupants will be research only. This is made possible by the recent gift of Sir Edward Yarrow to the Royal Society of £100,000. to be used to develop the science of engineering in any way they think fit, and the Council have very wisely decided to utilise this magnificent gift in the establishment of research on the above lines. The obvious difficulty, of course, is to find true research men, that is, as the Council of the Royal Society state themselves with regard to engineering, the men gifted with real insight and creative thought, and not those of the very numerous body who are in all essentials merely high-class mechanics capable of constructing ingenious mechanisms, devising pretty experiments, and of making accurate measurements, who in the very nature of things form the main mass of the Fellows of the Royal

Society itself. It is certainly a good sign that the Council should have delivered itself of such a disconcerting yet healthy opinion, which applies equally well to chemistry as to engineering and they are not losing any time in the matter since the advertisements regarding the vacancies have already been made public so that they may be filled in the autumn.

The Corrosion of Condenser Tubes. — The Corrosion Research Committee of the Institute of Metals, have just completed what promises to be a valuable piece of research work on the question of corrosion in condenser tubes, and a striking indication also of the important part played by the chemist in engineering. The report will be available in full very shortly, but it is understood that it will deal only with the corrosion caused by the presence of entangled air in the circulating water, which has been known to cause corrosion in condenser tubes within a few weeks, and even in less than one week in extremely bad cases. A prolonged investigation of condenser-tube corrosion undoubtedly makes the matter extremely mysterious, as the tubes are attacked in certain definite positions for no obvious reason, a striking characteristic being for example that if a given tube is attacked in one section, the next tube used for replacement is also attacked in the same place, so that the action is obviously independent of any possible flaw in the material, whilst the same applies to the material of which the tubes are composed, generally brass or other copper alloys, although certain special alloys with a high nickel content are more resistant.

It has now been proved conclusively as a result of this research, that the trouble is due to minor bubbles of air in the sea-water used as a cooling agent, and the action to some extent depends upon the velocity of the water passing over the surface of the tubes. This was determined by adding known volumes of air to sea-water and noting the effect of what may be described as the " bombardment " at different portions of the tube by the bubbles of air, the corrosion being enormously increased in proportion to the number and velocity of the air bubbles. It is not so much the total volume of air in the water that matters as the amount of sub-division of the air bubbles, and the smaller these are the more serious is the action, what may be described as " foam," consisting of a peculiarly intimate mixture of fine air bubbles with water, being much the worst. It was further noted that the addition of sulphuretted hydrogen to the sea-water added considerably to the effect, although the reason for this is not clear. As regards the methods of preventing such corrosion, it is not easy to suggest an effective remedy, since of course de-aerating sea-water is not a practical proposition if only because of the enormous volume of water handled for cooling purposes. Of course the pipe circuits and connections generally can be arranged so as to exclude as much air as possible, but the only method that seems to be available so far is the interesting one adopted by the Admiralty of treating the tubes beforehand, at a temperature of 100° F. (40° C.) for a week or two in sea-water which is stagnant, the result giving decidedly increased resistance to corrosion by air bubbles.

The " Marshall-Easton " Process of Low-Temperature Carbonisation.—The " Marshall-Easton " process is another new method suggested for the low-temperature carbonisation of coal and consists essentially in the use of a vertical retort equipped with two internal screw propellers, the heating being chiefly internal by means of the sensible heat of water gas. Internal heating using a hot neutral gas practically free from oxygen is extremely efficient from the point of view of heat transfer, much more so than any external method, whether at high or low termperatures, but one of the drawbacks, is that the final gas is of extremely low quality, the rich low-temperature gas evolved being mixed with the low grade heating gas. This new method is really a modification of the existing complete gasification processes. Messrs. Marshall and Easton contend that one of the practical difficulties of this method of gasification—irrespective of the temperature of carbonisation of the coal in the top vertical retort—is to ensure that coal will travel through the retort, as there is a frequent tendency to " jambing," whilst at the same time the heat transfer is very poor because the vertical retort is on the externally heated principle. The " Marshall-Easton " installation consists of a water-gas plant together with a vertical retort, but this latter—instead of being externally heated—has the blow gases, in which the combustion has been completed, passed up inside the body of the retort itself, although a certain amount of external heating is also included. Further the difficulty of the travel of the coal downwards is claimed to be overcome by the invention of the double vertical screw travelling in the body of the coal, and forcing it slowly downwards mechanically. The idea, of course, of an internal screw propeller is a very old one and has been adopted by numerous inventors, one of the earliest and best-known being Del Monte.

The inherent objection to all internal screw propellers is that as the coal softens during carbonisation it tends to block up the propellers, causing " jambing " in the retort. Some time ago Mr. Easton devised a method in which he used two screw propellers side by side, one screw working inside the other. It is contended that this simple and ingenious invention overcomes entirely the difficulty of jambing, since no matter how thick or pasty the material may be, it will not stop up two propellers working in this way one inside the other, as one propeller tends automatically to keep the other free. It is claimed that by this principle and the use chiefly of internal heating, using either the blow gases or the water gas itself that it is possible to work the combined process so as to obtain any desired quality of mixed gas suitable for household consumption from 260-550B.Th.U.'s per cubic foot, whilst at the same time recovering all the valuable low-temperature oils and obtaining from the vertical retort a continuous supply of low-temperature smokeless fuel. The water-gas plant can also be worked in any desired way, either using part of the low-temperature fuels that might be available, and the method should possess considerable interest to the gas industry as a variation of the existing water-gas plants.

The Trade Position.—The general position of acute depression in the engineering and allied industries has continued during the past month, the gist of the situation being that buyers are holding off as much as possible and that orders are coming in very slowly. The position with regard to the near future is giving rise to a considerable amount of uneasiness, and unfortunately there seems every prospect of a bad winter. At the present time the situation as regards pig iron is particularly depressing, and it appears certain that a number of blast furnaces will have to be closed down, whilst as regards steel, the position on the London Iron and Steel Exchange—almost approaching stagnation—can be said to apply practically universally, although perhaps one encouraging sign is that the severity of Belgian competition is diminishing. Shipbuilding remains in a disastrous condition, the matter being further complicated by the continued trouble with the boilermakers. The recent shipbuilding returns of the Liverpool Register for the quarter ending June show, however, that Great Britain has still an enormous lead in this section, having at the present time under construction 1,337,759 tons, as compared with the next competitor, Germany, with 352,405 tons. The amount under construction in the United States is actually only 133,600 tons, an incredible figure, especially as it was confidently expected that America would sweep the world with shipbuilding as soon as the war was over. The point is, however, that British shipbuilding, although retaining such a lead, is being undertaken at practically no profit because of the high price of steel.

General engineering is also very slack all round, and even the textile machinery portion is beginning to get a little anxious with regard to future orders, although still booked up for a considerable time to come. Fortunately, however, municipal work is engaging a considerable amount of attention, and the building of locomotives and rolling stock for railways is quite brisk, a number of large orders having been secured—especially in the Glasgow area—during the past few weeks. It is believed there is some extensive scheme on foot by the London Midland and Scottish Railway with regard to a proposal to electrify the main line between Carlisle and Preston, which would of course be of enormous benefit to engineering generally. The coal trade continues as in the previous month, with very big shipments, but also with some anxiety as regards the future. In the first six months of 1923, the total amount of coal shipped from Great Britain was 39,808,881 tons, which is a record for the British coal trade, being actually 12 per cent. more than for the corresponding period in the boom year of 1913. This is equivalent to 6,634,813 tons per month, as against 5,921,039 tons in the same period in 1913, and 4,530,660 tons in 1922. The influence of the Ruhr complications on the coal trade is shown by the fact that Germany, in the first half of 1923, took 8,000,000 tons as against 4,500,000 tons in 1913; France 9,500,000 tons as against 6,500,000 tons, and Belgium 3,500,000 tons as compared with 1,000,000 tons. The fuel boom due to the Ruhr seems, however, to now be coming to an end.

PARLIAMENTARY NEWS.

Smoke Abatement Bill.

In the House of Lords on Thursday, July 26, the Smoke Abatement Bill was read a second time.

Government Oil Boring.

In the House of Commons, Lieut-Colonel Lane-Fox (the Secretary for Mines) replying, on Tuesday, July 24, to Mr. Hannon, said: The approximate amount realised during the year ended March 31, 1923, by the disposal of Government buildings and plant utilised in the Government oil-boring experiments was £25,000. The amount reserved for interest on Exchequer advances and on administrative charges amounted on March 31, 1923, to £104,903. The total loss on the undertaking at that date, including such interest, was, approximately, £678,000.

German Reparation (Recovery) Act.

The Financial Secretary to the Treasury (Sir W. Joynson-Hicks), replying on Wednesday, July 25, to Mr. F. Gray, said: The total amount collected by the Commissioners of Customs and Excise under the provisions of the German Reparation (Recovery) Act, up to June 30 last, inclusive, was £13,264,282.

British Dyestuffs Corporation.

Mr. Collison, on Thursday, July 26, asked the President of the Board of Trade whether he is aware that an export inquiry for the price of 20 tons of Indigopur was recently offered by the official distributors for the British Government at 7s. 1d. per lb., against the price of the same article for home consumption at 8s. 6d. per lb.; and, in view of the fact that this shows a difference of £3,173. 6s. 8d. on this order in favour of the foreign buyer, will he give instructions to the official distributors to discontinue such discrimination against the home user?

Viscount Wolmer: I presume that by official distributors the British Dyestuffs Corporation, Ltd., is meant, and I am informed that no such offer as is mentioned in the question has been made by the Corporation in respect either of any reparation indigo or of indigo of their own production. If the hon. member has definite evidence to the contrary, I shall be glad to consider it.

British Dyestuffs Industry.

On Thursday, July 26, the Board of Trade Estimates were further considered in the House of Commons. In the course of the general debate on trade, Mr. H. H. Spencer drew attention to the dyeing industry of the country, and complained that the British dyestuffs manufacturer was given an undue preference by the prohibition of importation under certain conditions. He denied that the dye-making industry is necessary to the textile trade, or has been of advantage to that trade. It was established, he said, solely because of the danger of war, and it was not just that the colour user should, as he was at the present time, bear the whole cost of the industry. Further, he stated that goods produced in his own factory, and dyed with a colour identically the same as that used by a foreign competitor, were 1d. to 2d. per yard dearer in London than the foreign imported material. Mr. Spencer also considered that the colour users did not approve of, but only accepted the Dyestuffs Act, and expressed strong disapproval of the Licensing Committee.

Sir Thomas Robinson (chairman of the Dyestuffs Licensing Committee) said: As chairman of the Licensing Committee, I think it my duty to point out one or two things. The Act was approved by the dye users. On December 3, 1920, it was submitted to a meeting of dye users, and practically unanimously approved. The Bill was examined in every line and every paragraph, and assent was given. The Government were notified of that assent, and the dye users supported the Bill through all its stages, so there can be no doubt about it that this Bill has had practically unanimous support of the colour users of this country.

At the present time approximately 94 per cent. of the applications for licences have been dealt with within four days of the application being received; 62 per cent. have been dealt with on the same day. I am very glad to say that we are receiving very few complaints. If we are told by the experts that certain colours must come in, we endeavour to satisfy the applicants. In some cases we do not grant leave for the full quantity applied for, but we are mindful in such cases to license a quantity to keep the industry running. There are in the country, I believe, a number of purchasers who are what we term middle-men. Some of them during the war made pretty large fortunes. Some of them make a fair living dealing with dyestuffs. It is quite true that some of these people have suffered. The trouble is this—and there is evidence for it—that France, Belgium, and Italy are taking in reparation colours in larger volume than they can consume, or ever have consumed, and they sell the surplus outside to dealers.

Lieut.-Commander Astbury: It has been said by several hon. members that the textile industry of this country is being ruined by the present scheme. Really to those of us who are consumers of dyes, and have been consumers in some cases for 25 or 30 years, the whole thing is too absurd to answer. I have given figures to this House time after time, and I am going to give them over again this afternoon. When I tell the House that on the production of 150 yards of cloth the total cost of the dye in the production of that cloth is only 3 per cent. of the whole, what folly is it to come forward and say that this licensing scheme is ruining the textile industry! If there were no licensing whatever the cost of the printed and dyed cloth would not come down one brass farthing.

Now, where are the complaints coming from with regard to people not being able to get these dyes from abroad? When the war broke out nearly every alien in this country bought up all the colours he could, and these men, who had only a few shillings to bless themselves with before the war, sweated us in the price of these colours, and we shall never forget it. Complaints are coming now from the same agents that they cannot make a profit for themselves so long as they cannot import the colours here and sell them to us at an increased price. Those are the men who are complaining that they cannot get the colours. Only last night an hon. member showed me a letter from a firm complaining of the way the Licensing Committee was operating. The letter stated that they were ruining the textile industry of this country. I looked at the heading of the letter, and I said that that firm was only a small firm of agents in Manchester who were selling this colour before the war. They want to get hold of the surplus colours which are at present in foreign countries in order that they may undersell our colours in this country. What is going to happen now if you allow Germany free access to this market? To-day the colours that we cannot produce in this country the Germans are selling at sweating prices in France. The Germans are charging us to-day 8s. 6d. per lb. for colours which we cannot manufacture here, and the colours which we have been manufacturing here they are dumping at any price.

Mr. Pringle: Why do we not take these colours in reparation?

Lieut-Commander Astbury: Because if we take these colours from Germany we shall be ruining our own colour works here.

Mr. Pringle: But you do not make them.

Lieut.-Commander Astbury: You cannot make here every colour that a country has been making for the last 50 years in six months' time. You have to allow a reasonable time to make them. For all the colours we cannot produce Germany is sweating this country and they wish to undersell us in regard to the colours we are making, and then she will bring down with a crash the dyeworks of this country, and once she has done that she has the trade in her hands as before the war, and she can put up the price of the cheaper colours, and what state then will your textile trade be in?

Mr. Pringle: Why do we not take in reparation the colours which we do not make, and in regard to which Germany has a monopoly, and is selling at sweating prices?

Lieut.-Commander Astbury: We take 25 per cent. of those colours that we cannot make in this country, but that is a reparation question and does not deal with this subject. It does not deal with the business position. My argument is that if this country once again allows Germany to smash our works and get possession of our colour production your textile trade is ruined once and for all.

Silica-gel Refining Process.—The Davison Chemical Company, of America, has signed a contract with the Royal Dutch Shell Company, allowing that corporation the use of its silica-gel refining process. The arrangement is said to be practically the first one from which the Davison Company may be expected to derive signal benefits, as the holder of 49 per cent. of the stock of the Silica-Gel Corporation, which owns the patent.

ITEMS OF INTEREST.

Coal Output.—The output of coal for the week ended July 21 was 4,601,000 tons, compared with 5,041,000 tons in the preceding week and 4,390,800 tons a year ago.

Unemployment Figures.—The Ministry of Labour states that the number of persons on July 23 registered at the employment exchanges in Great Britain as wholly unemployed was 1,184,900. This was 4,239 more than in the preceding week, but 300,988 less than on January 1.

U.S. Bureau of Chemistry.—Dr. Charles A. Browne, of New York, has been appointed head of the Bureau of Chemistry, United States Department of Agriculture. Dr. Browne is at present chemist in charge of the New York Sugar Trade Laboratory, Inc., and will not take up his new duties until the autumn. Dr. Browne was formerly with the Bureau of Chemistry, resigning in 1907 to accept the position with the New oYrk Sugar Trade Laboratory.

Obituary.—We regret to record the death, at the age of 46, of Mr. E. V. Chambers, principal of the firm of Messrs. Chambers and Hammond, chemical engineers, of Halifax, who have erected the new tar distilling plant at the Mossley Gasworks, opened on Saturday, July 21. Mr. Chambers, who took part in the ceremony, was seized with a sudden illness after delivering an address, and he expired just before midnight.

Scottish Factory for Treatment of Seaweed.—It is reported that at Stromness, Orkney, a factory on a larger scale for the treatment of seaweed is to be erected which, with a suitable pier, is to cost £68,000. The seaweed will be treated for the extraction of potash, iodine, and other chemicals, and the seaweed residue, when mixed with crude oil refuse from Mexico, will be shipped to various centres for making into coal briquettes.

The Dyestuffs Act and the Irish Free State.—It is reported from Dublin that among the list of bills which the Government of the Irish Free State will introduce in the near future is one to deal with the dyestuffs question. The intention is to repeat the existing duty on German dyestuffs, and to facilitate import by granting licences to all bona-fide users. It is anticipated that very little opposition will be aroused to the measure. It is also possible that the Safeguarding of Industries Act will be modified considerably.

Science and Cacao Production.—We have received from the Publication Department of Messrs. Cadbury Brothers, Ltd., Bournville Works, Birmingham, two pamphlets prepared by A. W. Knapp, B.Sc., F.I.C., the head research chemist. The pamphlets which are both priced sixpence deal with "The Separation and Uses of Cacao Shell" and "The Application of Science to Cacao Production" respectively. They are well produced and illustrated and should make appeal not only to the chemist who does not specialise in this class of work, but also the lay public.

British Industries Fair.—The Board of Trade announce that the British Industries Fair will be held at the White City, Shepherd's Bush, from April 28 to May 9, 1924. It is stated that in selecting the date the Department appreciated that the holding of the British Empire Exhibition from April to October next year must materially affect the attendance of overseas buyers. United Kingdom firms eligible for participation in the Fair will receive forms of application for space during the first week of October, 1923. The Birmingham section of the Fair will be held from May 12 to May 23.

Institute of Chemistry Pass List.—The following candidates have passed the examination for the Associateship. In general chemistry: A. C. Anderson, J. Barnett, H. G. Beard, W. F. Bennett, W. Booth, T. H. Bott, F. J. Bubb, R. Child, W. Crombie, B. W. A. Crutchlow, R. H. Curtis, P. Faichney, A. W. Fairgrieve, A. T. Groves, A. N. Harrow, S. Hibbert, H. E. Hill, N. E. Jones, L. G. Kimmins, C. S. Kirby, W. M. Laing, P. J. Leaper, R. Lindsay, J. McGrath, A. P. Mieras, M. A. Mosley, R. B. Moyes, J. H. Oliver, D. Paul, A. Pound, J. A. H. Rosewarne, W. L. Russell, H. N. Saunders, R. Scott, C. G. Smith, Miss S. M. L. Snelus, G. D. D. W. Thacker, B. Thomas, H. Threadgold, J. D. Tully, J. Walker, W. H. Wells, A. S. Wilkie, G. E. Wilson, T. Wood, A. R. Wylie. In metallurgical chemistry: T. G. Howard. In food and drugs: J. E. Woodhead. In chemical technology: G. F. Martin. The following Associates have passed the examination for the Fellowship: N. Hackney, W. O. R. Wynn, A. Cohen, and J. E. Ritchie.

Caustic-soda Plant for Brazil.—In a report to the U.S. Department of Commerce, it is stated that the Companhia Brasileira de Productos Chimicos is receiving a loan of approximately $120,000 from the Brazilian Government to assist it in erecting a caustic soda factory in the city of Rio de Janeiro. As a guarantee for the loan, the company has pledged its present factory, which has been valued at $235,000.

Tariff Notes.—The duty leviable on copra exported from Dominica is reduced from 35s. to 20s. per ton.—Salt and ground nuts may now be imported into Zanzibar free from Customs duty.—According to a French decree dated July 16, the "coefficient of increase" of 2.5 which formerly applied to the import duties on crude iodine is reduced. This article is now dutiable at 1,600 and 400 francs per 100kilogs. under the General and Minimum tariffs respectively.

Sugar Beet in Great Britain.—A permanent Beet Committee has been set up at the headquarters of the National Farmers' Union. It is suggested that in future all contracts should be issued through the Farmers' Union, and the Committee endorses this view. Some difficulty in getting railway facilities for sending the crop away is anticipated, and negotiations on the subject are proceeding with the railway companies, in addition to which it is hoped to secure a better rate of transit for the large tonnage.

Application for Restoration of Lapsed Patent.—Notice is given that Konstantin Tarassoff and Peter Shestakoff have made application for the restoration of the patent granted to them for an invention entitled "Process for obtaining solid products of condensation from phenols, formaldehyde, and salts of sulpho-acids," numbered 102,635 (956 of 1916), January 20, 1916, which expired on January 20, 1920, owing to the non-payment of the prescribed renewal fee. Notice of opposition to the restoration must be made on or before September 11, 1923.

Cheshire Salt Deposits.—The conversion of a typical agricultural area into a centre of industry is rapidly taking place at Elton, Sandbach, says the *Liverpool Post*. A large tract of land, formerly included in the estate of the Marquis of Crewe, has been purchased by the British Soda Company. Shafts have been sunk, and works are in course of erection for the making of salt, soda, etc. Not a quarter of a mile away another firm of salt manufacturers (Messrs. Palmer and Mann) have sunk a brine shaft, and they are to start building operations immediately.

Nickelling Cast Iron.—Several American foundries are said to be experimenting with cast iron to which from 2 to 4 per cent. of nickel has been added. In the research department of the International Nickel Company of Canada, Limited, there has been developed a nickel bearing type of stainless steel said to contain from 20 to 40 per cent. of nickel, 6 to 12 per cent. of chromium, and 0.25 to 2 per cent. of silicon, which can be readily machined and fabricated. One rolled sample tested gave:—Tensile strength, 44.5 tons per square inch; yield point, 26 tons; elongation, on 2in., 20 per cent.; and reduction of area, 50 per cent.—*Engineer.*

Municipal Contract for Foreign Firm.—At a meeting of the Metropolitan Water Board on Friday last, strong protests were made against the recommendation of the Works and Stores Committee that the tender of Messrs. Christiani and Nielsen, a Danish firm with offices in London, should be accepted for the construction of eighteen concrete primary rapid filters and other works at Walton. The amount of the tender was £116,114. 19s. 2d., and the next lowest tender was that of Messrs. J. Parkinson and Sons, Ltd., Blackpool, £126,176. 14s. 3d. The recommendation of the committee was adopted with an addendum that all the labour employed in connection with the contract should be British.

Legal Intelligence.—Mr. Justice Romer, in the Chancery Division, London, on Monday, gave judgment in the action by Mr. William Watson, dyer, of Dundee, against the Organic Research Company, Ltd. and Mr. William Alfred Bromwich to recover £2,000. which he had paid for shares in the defendant company. The action against Mr. Bromwich failed, but his lordship declined to grant him costs, because the whole of the trouble was due to his carelessness. As against the company, he held that Mr. Watson succeeded. He applied to the company for unissued shares; he never intended to take shares belonging to Mr. Bromwich, and the company knew that they had no shares they could not allot him. There would be an order for repayment of the £2,000., but without interest, against the company with costs.

Australian Mining Company Ceases Operations.—It is announced that the directors of the Australian Broken Hill (Block 10) Company, Ltd., propose to discontinue operations on the property, and to take the necessary steps to dispose of the assets.

Compensation for Belfast Soap Makers.—In the Belfast Malicious Injury Claims Court on Tuesday, an award of £40,000, was made to Messrs. Shaw and Co., Ltd., Queen's Bridge Soap Works, Mountpottinger Road, in respect of damage to their premises during the disturbances of last year. The amount claimed was £57,000.

Quebec Asbestos Output.—During 1922 the asbestos sold and shipped from the mines of Quebec amounted to 160,339 tons, as compared with 87,475 tons in 1921. Lower prices prevailed, however, the 1922 output being valued at 6,053,068 lols., and that for 1921 5,199,789dols., an increase of 83 per cent. in output, but only 16.7 per cent. in value.

Imperial College of Science.—The Clothworkers' Company of the City of London have offered an annual contribution of £3,000. for the period of five years 1923-1927 to the Governing Body of the Imperial College of Science and Technology, South Kensington, to be applied towards the maintenance and development of the City and Guilds (Engineering) College.

Hull Chemical and Engineering Society.—The syllabus for the coming session, 1923-24, contains a number of interesting papers, and, as usual, covers a wide range of subjects. The Society is now 175 strong, and is in a good financial position. A library for the use of members is in course of formation for the coming session. The secretary of the Society is Mr. R. A. Bellwood, 24, Cavendish Square, Margaret Street, Hull.

Leeds University Agricultural Department.—The erection of the new building to house the Agricultural Department of Leeds University is about to be commenced in the new future. This has been made possible by a number of handsome donations from the late Mr. Walter Morrison, the late Mr. Henry Putson, Major J. W. Dent, and Mr. J. Emmanuel. A Treasury grant, through the Ministry of Agriculture, of £12,000., promised in 1914, has recently been increased to £15,000., and the Yorkshire Council for Agricultural Education have made a contribution of approximately £10,000.

Reduced Railway Rates.—The railway companies of Great Britain have given official notification that they are reducing their rates for the carriage of merchandise traffic by goods train from 60 per cent. about the rates in force on January 14, 1920, to 50 per cent. above those rates. The reductions take affect from August 7. All goods are included, with the exception of agricultural products and requisites, which are already carried at the new rate level, and of certain specified traffics for blast furnaces, or which the most important are iron ore and ironstone, these being already at 40 per cent. above the old standard. It is noted that no alteration is to be made to the flat-rate additions to the charges.

The Glowing of Phosphorus.—The glow of phosphorus, due to slow oxidation, appears when the substance is exposed to air, but very curiously disappears in oxygen under high pressure. Illustrating to the Royal Society of Edinburgh the effects of different pressures of oxygen, Dr. Elizabeth Gilchrist pointed out that some gases promote the glow, while others act as poisons to it. She found reason for concluding that reaction with oxygen occurs in two stages—phosphorus trioxide being produced in the first stage, without glowing, and phosphorus pentoxide in the second stage, with glowing. The damping effect was attributed to the production of an anti-catalyst—probably negatively charged molecules.

Electrolytic Production of Calcium Arsenate.—It is reported from America that an electrolytic method for the manufacture of calcium arsenate has been worked out with complete success. The inventor of the process is Mr. A. M. Kennedy, who commenced his experiments with the Alabama Power Company and carried them to completion in the laboratories and plant of the General Electric Company. The electrical requirements amount to something less than one kilowatt-hour of current for every pound of calcium arsenate manufactured, and it is anticipated that the material can be sold at something under 70 per cent. of its present cost. The new plant will be in full operation by the end of this year and the whole of the American cotton growers' requirements for 1924 may be met.

SOIL ACIDITY AND THE USE OF SUPERPHOSPHATES.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—In a review of a new fertiliser process the other day it was stated that because less sulphuric acid would be consumed in its manufacture the use of the new fertiliser would reduce soil acidity. I have also observed in the columns of the Agricultural Press from time to time statements to the effect that the continued use of superphosphate increases soil acidity.

It is, I think, fair to say that soil acidity is a subject on which there is much loose talk and loose writing. To the unitiated it may appear, and I believe, does appear to be inevitable that superphosphate will make a soil acid or sour, because sulphuric acid is used in the process of manufacture; but experiments have proved that this assumption is entirely erroneous. Soil acidity assumes many forms and arises from a variety of causes. The acidity apparently may be either vegetable or mineral and of the two the latter is infinitely more harmful to plant life than the former. Now whilst it is true that a substantial quantity of sulphuric acid is used in making a ton of superphosphate, what is not so generally recognised is that a very large proportion of such acid is neutralised by the lime present in the phosphate rock from which superphosphate is made, forming sulphate of lime or gypsum which well-informed French opinion regards as having of itself a considerable value as a fertiliser. Sulphate of lime is a stable compound which is not readily broken down in the soil, hence the acid so neutralised may be said to be permanently absorbed. The real fertilising value of superphosphates, however, lies in the phosphoric acid it contains which by the process of manufacture is rendered water soluble and immediately available for plant food when applied to the soil.

Experiments have demonstrated that, entirely contrary to general opinion, superphosphate, even where its use is long continued, actually reduces soil acidity. Thus in Bulletin No. 189 (1922) of the Agricultural Experiment Station of the Rhode Island State College it is demonstrated that the use of superphosphate on the College plots over many years actually reduced acidity, the soil being less acid where greater quantities of superphosphate had been applied than where the superphosphate dressings had been lighter. The "Jones" method of expressing acidity is adopted in the Bulletin which is to state the quantity of lime required per 2,000,000lb. of soil. The lime requirement of the plot where no superphosphate had been used was found by this method to be 2,700lb., whilst where the superphosphate dressing had been heavy it was 2,250lb., and where the superphosphate dressing had been lighter 2,340lb. were required.

It is probable that many of the sour or acid soils of the United Kingdom come into the mineral category, many of the clay soils for example probably contain soluble salts of aluminium, and it is generally recognised, I believe, that especially in the Midlands there is much land containing an excess of iron. The salts of iron and aluminium are very harmful to plant life, and it is, I venture to suggest, upon sour soils containing either or both of these elements in excess that superphosphate will exercise its maximum influence as a reducer of soil acidity. It is well known that phosphoric acid has an affinity for iron and aluminium bodies, with which it readily unites to form the insoluble compounds, phosphate of iron and phosphate of aluminium respectively. It has been pointed out that superphosphate supplies phosphoric acid in a water-soluble form, hence a dressing to such a soil would inevitably have a beneficial effect in reducing the contents of iron and alumina. There would appear to be a fruitful field for expert investigation in this connection.—Yours, etc.,

(For the Fertiliser Manufacturers' Association, Ltd.)
A. N. Gray (Manager).

London, E.C. 3,
August 1, 1923.

FERTILISER NEWS.

Nitrate of Soda.—Preliminary figures for the month of July indicate that production is on the increase, the estimated total of the month amounting to 162,000 tons. Exports from Chile are estimated at about 171,000 tons, leaving stocks on the West Coast in the neighbourhood of a million tons, compared with 687,000 tons at the same date (July 31) in 1914. Of the total shipments, 75,000 tons are due for Europe, 66,000 tons for the United States, and the balance of 30,000 tons for Japan and other countries. Present stocks in Europe are very low, deliveries inland from ports, at 37,000 tons, having exceeded imports by 20,000 tons. At the end of the month there was no more than 71,000 tons in importers' hands, though stocks in the possession of country dealers probably amount to a considerable quantity. This figure compares with 194,000 tons last year, 763,500 tons in 1921 (the result of the Pool's activities), and 142,000 tons in 1914. Adding the quantity afloat for Europe and Egypt, it is seen that the visible supply for this market is less than it has been for many years. Consumption, represented broadly by the figure given as "Port deliveries," is larger than for the same month of last year, which in its turn was an increase on 1921. This increase, however, may be partly attributed to the late season for beet, due to the inclement weather earlier in the year. Inquiry on this account is said to be fair, and it is reported also that the acreage available is rather larger than last year. It is significant that there is an all-round drop in consumption, every purchasing country participating in the decrease, when compared with July, 1913. Germany, of course, is the most notable in this respect, taking only 3,000 tons, against 46,000 tons in July, 1913. Deliveries in the United States were much smaller at 11,000 tons during July, against 52,000 tons in the corresponding period of 1914. Other countries reported deliveries amounting to only 1,000 tons. The total supply in sight as at July 31 last, including stocks in all the consuming markets, and in Chile, together with the quantity afloat, is estimated to amount to 1,372,000 tons, which is a much better figure than for the past two years.

Swedish Fertiliser Industry.—The superphosphate market in Sweden during 1922 was not as active as was expected. Among the causes contributing to its depression were bad weather during the summer and autumn, reduced growing of sugar-beets, and economic depression in agriculture. The domestic market was about equal to that of 1921, while exports amounted to 20,311 metric tons, against 18,382 metric tons in 1921. Most of the superphosphate was exported to Finland, Esthonia, Latvia, and Central Europe. The imports of phosphate rock amounted to 71,289 metric tons, against 70,224 in 1921. The domestic production of superphosphate was about 135,000 metric tons, or only about 55 per cent. of Sweden's full production capacity. The domestic sale of cyanamide was about equal to that of the preceding year. The export demand for cyanamide was considerable during the latter part of the year, and all plants are at present working at their full capacity. The sulphate of ammonia plants have been busy during the year, principally for export, as the domestic consumption of sulphate of ammonia is small. The demand was greater than the supply during the last months of the year. Imports of nitrate of soda amounted to 20,179 metric tons, against 26,051; and the import of nitrate of lime was 17,640 metric tons (14,938 tons in 1921). Imports of potash salts were 77,652 tons during the year, of which 3,100 tons came from France. Imports during 1921 were only 37,625 tons, the stocks on hand at the beginning of the year being large. The importation of pyrites has increased from 58,002 metric tons during 1921 to 78,067 metric tons in 1922, and the import of sulphur has also increased from 21,037 metric tons to 58,346 metric tons. The year 1922 was principally a year of reconstruction. The prospects for 1923 are rather bright, though the foreign competition is still strong.

General Notes.—Nitrate of soda continues to attract some attention in the home market. At London, nitrate of lime, which is in short supply, meets with a good inquiry, while kainit is in request for forward delivery. Basic slag attracts a fair trade at recent rates. Bone meal and steamed bone flour are not in much call, while superphosphate, sulphate of potash, and chloride of potash are inclined to be cheaper. In the North, fertilisers have been neglected, as is also the case in the Hull district, and prices continue unchanged and more or less nominal. In the West there is some inquiry for basic slag for autumn delivery.

The reports presented by two well-known fertiliser manufacturers in this country—the Anglo-Continental Guano Works, Ltd., and Messrs. W. and H. M. Goulding, Ltd.—indicate a falling off in the profits for the last financial year. In the case of the former the ordinary dividend has been passed over, while the latter have reduced the dividend from 8 per cent. to 5 per cent. There is little doubt that the great slump in agricultural produce, chiefly potatoes, during last year has considerably affected the disposition of the farmer to purchase fertilisers during the past season.

American fertiliser manufacturers have signed a contract with the German Potash Syndicate. Owing to the low prices offered by the Germans, the contract is expected to have an important bearing upon rates made by Alsatian potash producers. The prices in the new German contract are the lowest since the war and below pre-war levels.

Increased use of fertilisers in the cotton area this year as compared with last year is reported to the United States Department of Agriculture. More than 37 per cent. of the area has been fertilised, as compared with 32 per cent. last year. A number of individual States show larger increases.

Fertilisers are being used more generously in Italy than at any time since the war. One of the most important Italian fertiliser manufacturers states that in 1922 the firm supplied 541,414 metric tons of superphosphates, as compared with 501,976 metric tons in 1921, and adds that the strong demand for the spring of 1923 indicates that sales for the present year will reach 600,000 metric tons. The same manufacturer predicts a total of 1,070,000 metric tons for 1923, which would equal pre-war consumption.

The phosphoric-acid unit of the American cyanide plant, Brewster, Fla., was destroyed by fire, with estimated loss of between 400,000dols. and 500,000dols. The plant was used for experimental purposes and was controlled principally by the Virginia-Carolina Chemical Co. and J. B. Duke for the electrolytic production of pure phosphoric acid from pebble phosphate.

REPORTS OF COMPANIES.

Anglo-Continental Guano Works, Ltd.

The annual general meeting was held in London on Thursday (July 26), Sir Archibald Mitchelson in the chair. The chairman first referred to the regretted death of Sir Ernest Clarke, a former member of the board, and then, in moving the adoption of the report and accounts, continued as follows: Your directors realise the disappointment which shareholders will experience at a reduction in the company's earnings, particularly because, when the last general meeting was held just a year ago, a decidedly more hopeful atmosphere prevailed in the fertiliser industry. Unhappily, a bad agricultural season supervened. The potato crop was a heavy one, but, owing to unrestricted and quite abnormal imports of potatoes from the Continent, the home market was swamped; prices fell below the cost of production, and growers suffered a severe loss. The price of cereals, and, in fact, of all produce, fell disastrously; there remained no bright spot in agriculture. This company, having its chain of factories to draw from, had held its own against very severe competition. We knew that where others might fail, we could hope to succeed, by reason of our lower cost of transport from factory to farm. There was good reason to hope that our foreign competitors would be tired of selling over here at a loss and would raise their prices, enabling us to obtain a reasonable return on our own sales. What we could not foresee was the disastrous further fall in the foreign exchanges, coupled with a complete demoralisation in the fertiliser markets everywhere. The conditions in which our business had to be conducted underwent a great change for the worse, and our principal difficulty, though not the only one, was the vital disparity between sterling and the Continental currencies.

Turning to 1923, we find it extremely difficult to prophesy; the state of agriculture is not yet showing clear signs of improvement. Many farmers have been hard hit; credit is somewhat shaky, and merchants are buying cautiously. The agricultural demand is mainly for the cheapest articles, whether of British or foreign manufacture. We and our subsidiary companies have sold considerable quantities of fertilisers during the spring, but the lower-priced grades predominate, and in these competition has been severe. We do not fear any ordinary competition, but I should just like to express the view here that the business we are engaged in is of such vital importance to the country, both in war-time and in peace, that, in the circumstances to which I have alluded, it becomes a very serious question whether the Government should not extend some form of protective help, at least until such ruinous competitive conditions, brought about by present rates of exchange, have passed away.

W. and H. M. Goulding, Ltd.

Net profits for year to June 30 last, including dividends from subsidiary companies and refund of excess profits duty, amount to £35,139., out of which £7,000. is set aside to cover estimated discounts on realisation of outstanding debts; £7,940. was brought in, making £36.079. available. After providing for debenture interest and preference dividend, directors recommend a dividend of 5 per cent. on ordinary shares for year, 2s. 6d. per share payable forthwith, and second 2s. 6d. per share payable December 31 next, less tax; to depreciation account, £5,000.; forward, £3,904.

Arizona Copper Company, Ltd.

According to the last issued accounts a sum of £300,000. had been recovered on account of excess profits duty, and the balance of £61,235. previously admitted is now to be repaid. The income-tax claims on both sides have also been adjusted, and after charging tax on the whole sum recovered for excess profits duty, a further sum of small amount will be repayable by the revenue. An interim dividend of 1s. per share, free of tax, will be paid on November 1 next.

Consett Spanish Ore Company, Ltd.

Report for year ended June 30 last shows net revenue of £4,994., with £526. brought in. Balance available is £5,674. Final dividend is 1s. per share, making 2s. per share, or 10 per cent. for year. As, however, distribution absorbs £5,520., sum of £526. has been taken from undivided profits account, leaving latter at £5,674.

DIVIDENDS.

English Velvet and Cord Dyers Association, Ltd.—Interim dividends for half-year to June 30 at rate of 5 per cent. per annum on cumulative preference shares, and at rate of 6 per cent. per annum on ordinary shares, both less tax.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, whence, unless otherwise stated, further information may be obtained.

South Africa.

The Municipal Council of Johannesburg are calling for tenders for the supply of 200 Imperial gallons of aluminium paint, to be presented not later than noon on August 27, 1923 (Contract No. 108). (Ref. D.O.T. 11,706/E.D./C.C./2.)

Belgium.

A Belgian firm established at Verviers desire to get in touch with British firms manufacturing or exporting tanning extracts and other products used in the manufacture of leather. Correspondence in French. (Ref. No. 103.)

India and Straits Settlements.

The travelling representative of a well-known British firm manufacturing chemicals, drugs, etc., who visits India, Burma, Ceylon, Straits Settlements, Siam and Java annually, is desirous, with the concurrence of his principals, of undertaking the representation of one other British firm manufacturing non-competitive lines. (Ref. No. 119.)

Argentina.

The Commercial Secretary at Buenos Aires reports that the State Railways are calling for tenders, to be delivered on various dates between September 10 and October 3, for material for next year's stores, as follows: Chemicals, foundry materials, glass, paints and varnishes, etc. (Ref. 8495/F.L./G.P.)

NEW COMPANIES.

Barons, Ltd.—Private company. Capital £1,000. Manufacturing, consulting, and general chemists, etc. Office: Derby Street, Cheetham, Manchester.

Birmingham Rubber and Chemical Co., Ltd.—Private company. Capital £1,000. Office: 23, Whittal Street, Birmingham.

International Commodities, Ltd. — Private company. Capital £500. Importers and exporters of perfumery and toilet commodities, manufacturers of toilet soaps, etc. Office: 229-230, Bank Chambers, 329, High Holborn, London,

Lavoclean, Ltd.—Private company. Capital £10,000. Manufacturers of a chemical compound known as "Lavoclean." Address: Windyridge, Grays, Essex.

London Casein Works, Ltd.—Private company. Capital £2,000. Office: City Press Chambers, 148 and 149, Aldersgate Street, E.C.

Maltby's Morpowr Co., Ltd.—Private company. Capital £1,000. Manufacturers of polishes and soaps, etc. Solicitor: F. Hall, Bouverie Chambers, Folkestone.

Silloth Products, Ltd.—Private company. Capital £3,000. Manufacturers and dealers in foods and food products, etc. Office: Confectionery Works, Esk Street, Silloth, Cumberland.

Whitewall Manufacturing Co., Ltd.—Private company. Capital £6,000., in 5,000 preference shares of £1. and 10,000 ordinary of 2s. Dealers in ores, metals and minerals, tar extractors, etc. Office: 20, Grosvenor Gardens, Westminster, S.W.

Charnock Bros. and Co., Ltd.—Private company. Capital £5,000., £1. shares (1,000 preference). Oil and grease manufacturers and merchants. Office: 19-21, Scrabo Street, Belfast.

GAZETTE NEWS.

MORTGAGES AND CHARGES.

Aluminium Corporation, Ltd., London, S.W.—Registered June 30, £250,000. 2nd deb. stock (filed under sec. 93 (3) of the Companies (Consolidation) Act 1908); present issue £150,000. (ranking pari passu with £100,000. debs. dated July 27, 1920, and £150,000. debs. dated June 13, 1921).

Egyptian Central Oilfields, Ltd., London, E.C.—Registered July 9, £2,000. debs., part of £20,000.

Maitland (A.) and Co., Ltd., London, W., chemists.—Registered July 11, charge, to London Joint City and Midland Bank Ltd., securing all moneys due or to become due to the Bank.

Pastex Dyes, Ltd., London, N.—Registered July 13, £600. deb., to Central and Western Corporation, Ltd., Fitzalan House, Arundel Street, W.C.

Rushden Chrome Tanning Co., Ltd.—Registered July 11. mortgage to National Provincial and Union Bank of England Ltd., securing all moneys due or to become due to the Bank.

SATISFACTIONS.

Duckton Sulphur Copper and Iron Co., Ltd., London, E.C.—Satisfaction registered July 11, £5,800, part of amount registered March 2, 1912.

Pastex Dyes, Ltd., London, N.—Satisfaction registered July 16, £1,500., registered March 15, 1923.

PETITIONS PRESENTED FOR SEQUESTRATION.

Caledonian Chemical Co., 219, Caledonia Road, Glasgow, S.S., and **Robt. Cameron**, 80, Langside Road, Crosshill, and **Andrew Sneddon Matchet**, 13, Bute Gardens, Muirend, individual partners. July 12. (Petition for Summary Sequestration.) Agent, W. Cuthbert, 180, Hope Street, Glasgow, solicitor.

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

Auchinachie, P., Essex Villa, Tavistock Road, South Woodford; consulting chemist; £10. 9s. 7d. June 7.

Cope, M., 20, Cornwall Road, Harrow; chemical manufacturer; £30. 17s. 8d. June 11.

SOUTH WALES NOTES.

[Specially Contributed.]

Owing to the scarcity of orders for future delivery the tinplate workers are to have an extension of the usual holidays, current orders being near completion. The committee controlling standard prices have extended the period for which minimum prices will be available in the hope of renewing market activity. There are hopeful signs of an improvement in the demand for galvanised sheets and a better volume of business is being obtained. Manufacturers are buying more spelter, and the price of this metal reflects the anticipations of the market. At the South Wales Tinplate Industrial Council it was intimated by the employers that the 7½ per cent. concession would be continued for the next three months. In addition, they had agreed to a further rise of 3¾ per cent., making the total 11¼ per cent. above the base rate of the sliding scale. The patent fuel trade is steady and the factories are keeping up production. Nickel makers are fairly well employed, the metal being in better demand and the by-products selling well.

The imports for the week to Newport included 10 tons ferro silicon, 50 tons calcium carbide from Antwerp; to Swansea 2 tons calcium carbide from Arandore, 40 tons nitrate of soda from Christiania, and 2,400 tons zinc concentrates from Port Pirie; to Cardiff 100 tons salt from Hamburg, 20 tons cement from Antwerp, 19cwt. copal gum from Puerto Santa, 480cwt. paraffin wax from Norfolk, U.S.A.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

Every one of the trades with the exception of the coking trade is rather worse than better this week. The condition of the iron and steel industry certainly has not improved, and it was stated early in the week that even trade of the hand-to-mouth character which has been experienced during the past two months is of smaller extent, and that unless needs expand again a further restriction of production must take place. As to this, however, there was no definite information available, and it is hoped that if August can be passed without any more furnaces being damped down the most critical period of all in the year has been negotiated. But as far as Cumberland is concerned it is evident that makers of ordinary iron will have to rely on the Continent, the Midlands, Scotland and South Wales for the absorption of nearly all the output. The steelworks have few orders remaining on the books, and it may be a little time before the rail mills are working again to take some proportion of the iron that is being smelted. Of course the coking trade is not dependent entirely upon the furnaces in West Cumberland, as some of the make is now going to the Furness district, but most of the plants send their production to the Workington and Cleator Moor furnaces. In the coal as well as in the iron and steel trades there is also some depression. The local iron and steel works and iron ore mines are taking less and the house demand has fallen considerably. As to coke, the feature to be noted this week is the strong demand that is coming from the Continent. Shipments in the course of a week or two will be bigger than at any other time this year. The Continent is paying from 30s. to 40s., f.o.b., and local smelters 25s. to 33s. per ton according to carbon content. East Coast coke supplies this week are slightly over 8,000 tons. By-products and chemicals are a fair trade. Crude benzol is rather slower than usual. Sulphate of ammonia is moving away satisfactorily. Road tar is on the easy side. Creosote is being exported. Tar acids are steady.

THIRTY-FIVE YEARS AGO.

(From the "Chemical Trade Journal," August 4, 1888.)

Miscellaneous Chemical Market.—Prices of soda-ash and soda crystals remain steady, and caustic soda is without change, though the tendency is rather in favour of higher prices, owing to firmness in saltcake. Chlorate of potash remains at 5¼d., and bleaching powder maintains its position at £7. 5s. on rail at makers' works. Sulphate of copper is steady at £20. per ton. Lead and litharge are dearer, with the effect of stiffening prices in nitrate and acetates of lead, though demand for the latter is much below the average, and stocks are abundant. Carbolic acids continue dull, and prices do not improve notwithstanding that crude is firmly held. Brown acetate of lime continues to move slowly at £7. per ton, and grey at £12. per ton at usual points of delivery. Acetic acid, 25 per cent., sells at 7s. per cwt. Alum and sulphate of alumina find very little outlet, and all chemicals for dyeing and calico printing are at a discount, owing to dulness of trade in these branches. Zinc chloride is in fair demand both for home trade and export. Ammonia and salts are exceedingly quiet. Muriate of ammonia, £21. 10s. at makers' works.

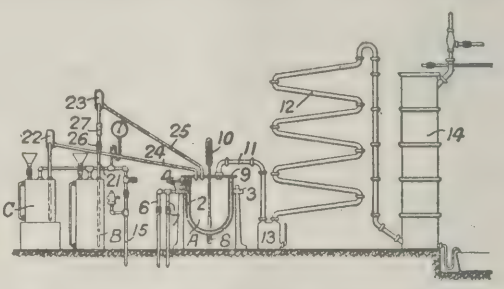
ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Mercury Fulminate. E. A. Barnes, Oakland, California, U.S.A. British Patent, **198,287**, of 1922.

Mercury fulminate is made by a continuous process in which the reagents, mercury dissolved in nitric acid, and alcohol are fed gradually to a reaction chamber maintained at the necessary temperature. The reaction chamber A is mounted on trunnions 3, 4, and pipes 6, 7 communicate



through the trunnion 4 with a jacket 2 so that hot water or steam may be admitted for heating, or cold water for cooling the chamber. The cover 9 carries a thermometer 10 and an outlet 11 carries the fumes to a trap 13, condenser 12, and scrubber 14. A valved outlet 8 allows of drawing off the medium from the jacket. Supply vessels B, C contain alcohol and a nitric acid solution of mercury respectively, and are connected with a compressed air pipe 15 so that the liquids are forced upwards to chambers 23, 22, open to the atmosphere, from which they flow by pipes 25, 24 to the reaction chamber. The relative quantities of the liquids are controlled by a valve 26 and telescopic part 27 in the pipe 21 which supplies the chamber 23. When the reaction chamber has become sufficiently full, the feed of reagents is stopped and when fumes cease to be evolved the heating medium is shut off and the reaction chamber is cooled and then discharged. The residual liquor after the separation of the fulminate consists of glycollic acid with some excess nitric acid. It is converted into oxalic acid by evaporating to about an eighth of its bulk and cooling when the oxalic acid crystallises. The reagents in the vessels B, C may be maintained at any suitable temperature, and they may be mixed prior to feeding to the reaction chamber, but in that case must be kept cold to avoid reaction before they reach the reaction chamber.

Thioindigoid Dyestuffs. W. Carpmael, London. (Farbenfabriken vorm F. Bayer and Co., Leverkusen, Cologne, Germany.) British Patent, **198,415**, of 1922.

Thioindigoid-dyes dyeing cotton in fast brown shades from the hydrosulphite vat are prepared by condensing 2:1-naphthooxythiophene, or a nuclear substitution product thereof such as a halogen derivative, with isatin, or a substituted isatin such as a 5:7-dihalogen isatin, or a cyclic *o*-diketone containing two or more nuclei, for example, acenaphthenequinone, 1:2-diketohydrindene, 2:3-diketo-(1)-thionaphthene; *β*-naphthisatin is however excluded. In an example 5:7-dichlorisatin is used, the condensation being effected in the presence of glacial acetic acid.

Metaldehyde. J. Y. Johnson, London. (Elektrizitätswerk Lonza, Basle, Switzerland.) British Patent, **198,576**, of 1922.

Metaldehyde is produced by the action of the following catalysts on acetaldehyde at temperatures below 10° C., (1) titanium chloride, (2) a bromide of an alkali or alkaline-earth metal, such as lithium or calcium bromide, (3) a halide of an alkali metal, alkaline-earth metal, aluminium, zirconium, thorium, cerium, lanthanum, yttrium, ytterbium or titanium, in conjunction with an acid, such as hydrochloric or hydrobromic acid, an acid salt, or a compound having acid properties, such as ferric chloride, aluminium chloride, or sulphur and antimony haloids.

Synthesis of Quinoline Derivatives. J. A. Gardner and M. Williams, London. British Patent, **198,462,** of 1922.

In the synthesis of quinoline and its derivatives by the Skraup reaction or the Döbner and von Miller reaction chloropicrin is employed as the oxidising agent. In examples the use of chloropicrin in the production of the following compounds is described:—Quinoline, 6- or 8-methylquinoline, 5:8-dimethylquinoline and 8-hydroxyquinoline, from glycerol and the corresponding aromatic amine; alizarin blue from β-aminoanthraquinone and glycerol; 2-methylquinoline from aniline and paraldehyde.

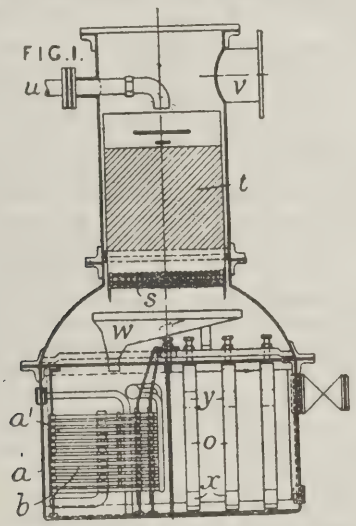
Electrolytic Production of Per-compounds. Chemische Fabrik Weissenstein Ges. and G. Baum, Carinthia, Austria. British Patent, **198,246,** of 1922.

Anodes for use in the formation of per-compounds consist of tantalum partially covered with platinum or of an alloy of tantalum with platinum. The coating when used may be effected by electrolysis or by hammering, welding, rolling or the like.

Evaporating Liquids. H. Bollmann, Hamburg, Germany. British Patent. **198,250,** of 1922.

The base of the still *a* is divided by vertical radial partitions into number of separate compartments each provided with a separate heating-coil *a'*. The vapours rise from all the compartments through a grating *s* and a filling-material *t* to an outlet *v*. The liquid to be distilled, supplied through

FIG.1.



a pipe *u* and heated by flowing over the material *t*, is directed by a collecting-pan *w* into the compartment *b* kept at the lowest temperature. The liquid flows in succession through the compartments which are kept at successively higher temperatures through pipes *o* having inlets *x* at the base and outlets *y* at the top. In treating a mixture of benzol, alcohol and water obtained in the extraction of oleaginous seeds, the first compartment is kept at 60° C., the second at 70° C., the third at 80° C., and the last at 100° C.

Formic Acid. H. Nielsen, London; and B. Laing, Hatfield, Hertfordshire. British Patent, **198,385,** of 1921.

Comprises (1) the production of formic acid by the oxidation of methane with a metallic oxide or by the interaction of carbon monoxide and water vapour in the presence of a catalyst, preferably a metallic oxide; and (2) the destructive distillation of carbonaceous material in the presence of formic acid vapour for the purpose of increasing the yield of condensible hydrocarbons. As regards the production of formic acid, methane or a mixture of carbon monoxide and water vapour is passed at a temperature of 250-800° C. over a metallic oxide, which preferably comprises an "activated copper suboxide," prepared either by precipitating copper from a solution of copper sulphate with metallic zinc, and then washing, drying and roasting the precipitate in air, or by moistening other copper precipitates from copper salts or granulated or powdered copper with dilute zinc-sulphate solution, followed by washing, drying and heating in air. After a short time the copper suboxide becomes inactive and must be reactivated by moistening it with dilute zinc-sulphate solution, washing, drying, and roasting in air. Gases such as air gas, water gas, coal gas or natural gas may provide the source of the methane or carbon monoxide; and their sensible heat, if any, may be utilised for the formic acid reaction, which is endothermic. In the destructive distillation of carbonaceous materials, which may comprise coal, lignite, peat, shale, wood, or liquid hydrocarbons, the formic acid, which may be prepared as described above, is introduced in the vapour phase into the distillation vessel. The carbonaceous material may contain a small percentage of admixed carbonates of sodium, potassium or calcium; and the distillation vessel may be heated internally by the sensible heat of the whole or a part of the air gas or water gas before conversion into formic acid. It is stated that hydrocarbon gases may be similarly treated; thus, acetylene may be converted into acetic acid.

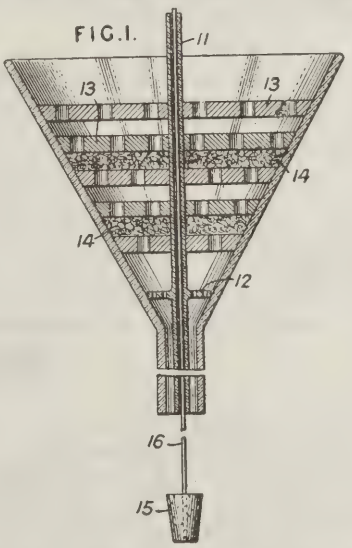
Concentrating Sulphuric Acid. I. Hechenbleikner, North Carolina; and T. C. Oliver, New York, U.S.A. British Patent. **198,545,** of 1922.

Sulphuric acid which has been used in refining petroleum and treated to recover part of the hydrocarbons is concentrated by blowing hot air through it to a point somewhat below the concentration, near 57° Baumé, at which foaming and charring of the hydrocarbons take place. The bulk of the hydrocarbons are driven off by this treatment and the acid is further concentrated in a second apparatus. The first concentration takes place in a chamber of acid-resisting brick provided with perforated earthenware pipes through which hot air can be blown. The acid enters through a tower, in which it is preheated by the escaping fumes, and which may be packed or not as desired. The partly concentrated acid, freed from the hydrocarbons, passes to an "acid egg," and thence to a second chamber like the first chamber, and provided with a preheating entrance tower.

Funnel Filters. S. A. Giacobbe, New York, U.S.A. British Patent, **198,414,** of 1922.

A funnel is fitted with an air escape tube 11, supported by a perforated disc 12, and layers of filtering-material 14

FIG.1.



between perforated discs 13. A cork 15 is attached to a wire 16 which passes through the tube 11 and may be graduated.

Fertilisers. G. W. S. Brewer, Broadstairs, Kent. British Patent, **198,242,** of 1922.

A dry or powdered fertiliser consists of peat or peat refuse, peat soil or other soil derived from land which has been under cultivation, "killed" lime or chalk, and one or more fertilising agents such as phosphates, nitrates, potash salts, ammonia salts, soot, or fish manure. The peat, soil, and lime or chalk are mixed and allowed to stand for a few days with occasional turning; the mixture is then dried, and, if necessary, disintegrated, and the fertilising-agents are added. The soil is stated to introduce nitrifying bacteria.

Disazo Dyestuffs. W. Carpmael, London. (Farbenfabriken vorm. F. Bayer and Co., Leverkusen, Cologne, Germany.) British Patent, **198,398**, of 1922.

Disazo dyes are prepared by coupling the tetrazo compound from 4:4'-diamino-diphenyl-3:3'-dicarboxylic acid on the one hand with an azo dye component which contains a sulphonic or carboxylic group or two hydroxy or two amino groups, or one hydroxy and one amino group, or a hydroxy group in conjunction with the $CH_2.CO$- group of the aceto-acetic-anilides or of the pyrazolones, and on the other hand with a pyrazolone or an acetoacetic-anilide compound. The products dye cotton in orange to red shades which by after-treatment with metallic salts, for example, copper or vanadium salts, are changed into deeper orange-brown or green shades fast to light and washing. In an example the tetrazo compound is coupled with 1-*m*-aminophenyl-3-methyl-5-pyrazolone and *m*-aminophenol: the product may be after-coppered, or diazotised on the fibre and developed with pyrazolone

Fuel Briquettes. Soc. dite l' Avébène, Paris. British Patent, **197,901**, of 1921.

Anthracite, coke, etc., in powder form is mixed with the pulverised mass obtained by concentrating bisulphite lye after complete neutralisation of sulphurous acid (free or in part combined), contained therein. Water is added if the fuel material is not sufficiently humid to form a plastic mixture. The fuel is compressed into briquettes which are baked up to about 200° C. for 20 to 40 minutes. In an example 100 parts of material are mixed with 3 to 3½ parts of solidified lixivium.

Poisonous Gases. J. W. van Meter, San Francisco, California, U.S.A. British Patent, **197,706**, of 1921.

A mixture of poisonous gases is obtained by the action of chlorine, preferably moist and under pressure, on a cyanide, with which a metal may be mixed to accelerate the reaction. The product comprises a mixture or combination of chlorine and cyanogen, together, it may be, with products resulting from the presence of the metal. Arsenic, antimony, copper, tin, lead, and iron are instanced as suitable metals, and when iron is employed the resulting gaseous mixture is stated to be suitable for orchard fumigation.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

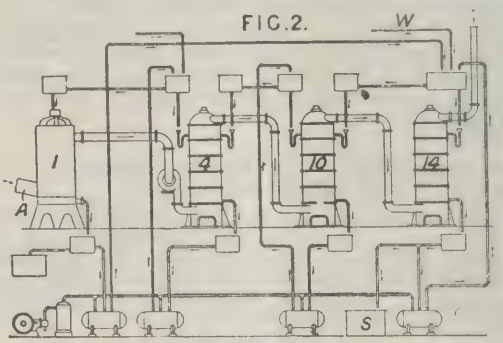
Pyrazolone-Barbituric Acid Compounds. Chemische Fabrik auf Actien (vorm E. Schering), Berlin. British Patent, **198,379**. Convention date, May 29, 1922. Addition to 158,558.

The process of the parent Specification, for melting together C.C. diethylbarbituric acid and 4-dimethylamino-2.3-dimethyl-1-phenyl-5-pyrazolone to form a new compound, is modified by substituting any C-C-derivative for the diethyl compound. Examples show the preparation of compounds using dipropyl, diallyl and phenylethyl barbituric acids respectively.

Sulphuric Acid. W. F. Lamoreaux, Isabella, Tennessee, U.S.A. British Patent, **198,332** Convention date, May 29, 1922.

In the manufacture of sulphuric acid in which sulphur dioxide is oxidised in the presence of nitrous compounds, the reacting liquids are intensively dispersed within the gas stream, and the quantity of water present is so regulated that all the sulphur trioxide produced is not absorbed in the reaction chamber. The arrangement of plant shown in Fig. 2 includes a Glover tower 1, and three gas washers of the

FIG.2.



Feld type. Gases containing sulphur dioxide and nitrogen oxides enter the Glover by a pipe A and then pass on to the washer 4 in which they come in contact with finely dispersed nitrous vitriol. The fog of sulphur trioxide produced is not condensed but passes into the second washer 10 containing acid of 59—61° Bé. which absorbs the nitrous compounds liberated in the washer 4. The sulphur trioxide is finally condensed in a third washer 14 in which 97-99 per cent. acid is circulated. This concentration is maintained by the addition of water or steam through a pipe W or by the addition of weak acid from the Glover. A portion of the condensed acid is used to supply the washer 10 in order to maintain the concentration at 59-61° Bé. Acid in excess of that which is required is stored in a tank S. The quantity of nitrous vitriol circulating through the absorber 10 which is withdrawn to supply the washer 4 is regulated according to the flow of sulphur dioxide, so that the acid leaving the bottom of the washer is almost entirely denitrated. Complete denitration is effected in the Glover tower 1, an acid of 60° Bé. being obtained. In a modified process, when a completely denitrated product is not essential, the Glover tower is dispensed with. Instead of vertical washers of the Feld type horizontal Theisen washers may be employed. When intensive production is desired additional nitrogen compounds are introduced into the washer 4 and the process may be conducted under pressure.

MARKET REPORTS.

LONDON "OPEN MARKET" REPORT. WEDNESDAY.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals.—Of the many poor months of business experienced this year there seems little cause to doubt that July has certainly been the worst. The demand throughout this market has been strictly limited to the smallest of quantities, and in some articles business seems at a complete standstill. **Acetic Acid,** 80% technical, £47. to £48.; 80% pure, £50.; 98% glacial, £60. in casks and £75. in demi-johns, ex wharf, London; the spot position keeps very steady at these prices, with business on the quiet side. **Acetone,** British Government specification, about £130. per ton, nominal, in drums; this market keeps quite steady, and there has been a fair inquiry on the market; spot supplies are now very scarce. **Arsenic,** Cornish white powdered, £72. to £73. per ton for spot lots; some offerings are being made, but business has been very limited. **Alum,** lump, £10. to £10. 10s. per ton, in casks; slightly easier rates are being quoted, with practically no demand on the market **Anhydrous Ammonia,** 99.95%, about 1s. 5d. per lb.; business is very moderate. **Barium Chloride,** 98/100%, £15. to £15. 5s.; the few inquiries received have been only for cask or one-ton lots. **Bleaching Powder,** 35/37%, £10. to £10. 10s. per ton; dealers are offering Continental material at these figures, with very little doing. **Borax,** commercial, granulated £26. 10s., crystals £27., powdered £28., extra fine £29.; B.P., crystals £31., powdered £32., extra fine £33. per ton, for home trade only, in free 2cwt. bags, carriage paid to destination in the U.K.; British makers' quotations are unchanged at these levels; importers are offering, under similar conditions, commercial, granulated £25. 10s., and powdered £27. per ton. **Borax Glass,** lump £74., powdered

£75. per ton, in tin-lined cases; British makers' prices quoted, for home trade only, packages free, carriage paid in the U.K. **Boric Acid,** commercial, crystals £50., powdered £52.; B.P., crystals £56., powdered £60., extra fine £62. per ton, in free bags, carriage paid to destination; British makers offering at these prices for home trade only; dealers are offering at competitive rates. **Cream of Tartar,** 99/100%, 90s. to 93s. per cwt., less 2½%, in one-ton lots; the spot position keeps fairly steady at these figures, with some limited business passing. **Citric Acid,** B.P., crystals, about 1s. 6¾d. to 1s 7¼d. per lb., less 5%; this market remains rather unsteady, and business has again been poor. **Epsom Salts,** commercial quality, about £5. per ton; the few inquiries on the market have been for very small quantities. **Formaldehyde,** 40%, about £96. per ton, nominal; business in this product is still being held up by the delay in the issue of the referee's decision in the appeal case. **Glauber's Salt,** commercial quality, about £3. 15s. to £4. per ton; reports to hand state practically no inquiry being received. **Lead Acetate,** brown, about £41. to £42.; white, £42. to £43. per ton; dealers are now offering at these cheaper prices, with not much business about. **Litharge,** pure flake, British, about £37. per ton; dealers are quoting Continental material in the region of £36. per ton. **Lithopone,** 30% Continental red seal, £22. to £22. 10s. per ton; prices for this product are well maintained, and some limited business has been done. **Ammonium Chloride,** grey galvanising, £30. 10s. to £31. per ton; although the demand has been poor, these prices seem quite steady for spot stocks. **Nickel Sulphate,** home trade, single and double salts, £38. per ton, delivered; export, single and double salts, £38. per ton, f.o.b.; British makers quoting at these unchanged rates. **Oxalic Acid,** about 6d. per lb.; this item remains very flat indeed. **Bichromate of Potash,** about 6d. per lb.; dealers are finding very little business. **Carbonate of Potash,** 90/92% £28., 96/98% £31. to £31. 10s. per ton; much cheaper prices are being quoted for spot supplies; the demand remains poor. **Chlorate of Potash,** crystals and granular, about 3d. per lb.; this item remains flat with quoted rates unchanged. **Caustic Potash,** 88/92% £32. to £32. 10s. per ton, in drums; the demand for the spot supplies available remains poor; prices are a shade easier. **Permanganate of Potash,** commercial quality, about 9¼d. to 9¾d. per lb.; business in this article has been restricted; quoted prices unchanged. **Prussiate of Potash,** yellow, about 1s. 2d. to 1s. 2½d. per lb.; a further material cut in the price of this article has been made this week; business is usually for smallish lots. **Sulphate of Potash,** 90% £11. 10s. per ton, ex ship; there is no change to record. **Mercury,** £10. 5s. to £10. 7s 6d. per bottle of 75/76lbs. net; the spot position is a little easier after a week of poor business. **Red Lead,** imported, about £36. per ton; dealers are doing some little business at about this level. **Salammoniac,** dog-tooth crystals £48. 10s. to £49., medium £43. to £44., fine white crystals £26. to £27. per ton; at these unchanged rates the spot position appears to be fairly steady despite the poorness of business. **Saltcake,** ground and unground, home trade, about £4. 10s. per ton; export, about £5 5s. per ton, f.o.b.; the market stands steady at about these levels. **Acetate of Soda,** about £25. per ton; at this slightly easier price the market is steady but quiet. **Soda Ash,** 58% light alkali £7. 12s. 6d. per ton, in bags, carriage paid to destination; British makers' quoting at this rate for home trade only; Their prices for export vary as to destination. **Soda Crystals,** about £5. 5s. per ton, in bags, carriage paid to destination; British makers selling for home trade only at about this figure; dealers are offering imported material at competitive rates. **Caustic Soda,** 70/72% £18. 10s., 76/77% £20 10s. per ton, in drums, ex wharf, shipping port; dealers prices are maintained at about these levels, but business is lacking. British makers' prices for home trade only are unchanged, from £19. to £21. 10s. per ton, in drums, carriage paid; their prices for export vary as to destination. **Bicarbonate of Soda,** £10. 10s. per ton, in bags, carriage paid to destination; British makers' prices stated; dealers are offering at about level figures. **Bichromate of Soda,** home trade about 4½d. per lb.; export about 5d. per lb.; British makers' prices are given. **Chlorate of Soda,** crystals and granulated, 2⅝d. per lb.; the market has again been quiet. **Cyanide of Soda,** 98/100%, export, 8½d. to 9d. per lb.; home trade, about 10½d. per lb.; British makers offering at about these prices. **Nitrate of Soda,** 96% £13 7s. 6d. per ton., f.o.r. Liverpool; there is no change in the position to record. **Nitrite of Soda,** 100%, about £26. 10s. per ton; the market is steady at this unchanged price. **Prussiate of Soda,** about 6½d. per lb.; a further cut in the price of this product has been made, with the demand still poor. **Hyposulphite of Soda,** pea crystals, about £14. 10s. to £15. per ton, in 1cwt. kegs; commercial quality, about £10. to £10. 10s. per ton, in casks; dealers are offering at these prices on a slow market. **Sodium Sulphide,** 60/62% solid, £14.; ditto, broken, £15. to £15. 10s. per ton, in drums; 60/65% concentrated, £15. per ton, in casks; business has been poor, but quoted prices are about the same. **Sulphate of Copper,** about £26. per ton for spot parcels; cheap offerings are coming to hand from the Continent. **Tin Crystals,** about 1s. 4d. per lb.; this market shows no change on the week. **White Lead,** imported, about £43. per ton; limited orders have been booked by dealers at about this figure. **Zinc Oxide,** B.P., about £50.; white seal, about £42. 10s. per ton.; 99.5%, about £37. per ton, f.o.r., makers' works; British makers are quoting at slightly easier rates.

Pharmaceutical Chemicals.—There is no improvement in business to record. The market generally is very sluggish and the tone unsteady. Some prices are already at slightly easier rates. **Acetanilid,** crystals and powder, about 1s. 5d. per lb.; prices quoted are unchanged, with business very poor. **Acetyl-Salicylic Acid,** B.P., 3s. to 3s. 1d. per lb.; inquiry has been small during the week, but rates are level. **Benzoic Acid,** B.P., about 2s. 3d. per lb.; there is no movement, and quoted prices are unaltered. **Diethylbarbituric Acid,** B.P. (barbitone), about 21/- per lb.; practically no interest shown, though quoted rates seem steady. **Salicylic Acid,** B.P., about 2s. 2d. to 2s. 4d. per lb.; the market keeps up to these figures with the demand small. **Tannic Acid,** leviss, 3s. 3d. per lb.; very little interest shown in spot offers in the region of this figure. **Amidopyrin,** about 14s. to 14s. 6d. per lb.; Continental prices keep this spot figure up on a slow market. **Ammonium Bromide,** 7d. to 8d. per lb.; the tone of this product is very flat and prices are again somewhat easier. **Benzonaphthol,** about 5s. per lb.; nothing doing here, and quoted rates unaltered. **Benzaldehyde 03,** about 3s. per lb.; no business reported, with quoted prices the same as last week. **Betanaphthol,** resublimed, about 1s. 10d. per lb.; inquiry has been poor, and dealers' prices are unaltered. **Calcium Lactate,** 1s. 9d. to 1s. 10d. per lb.; easier rates are being quoted here on a dull market. **Chloral Hydrate,** duty paid, about 4s. per lb.; this product is seldom in request, and spot values are steady. **Creosote Carbonate,** about 8s. 6d. per lb.; no further fall in spot values, but business very quiet. **Creosote,** B.P., about 2s. 2d. per lb.; the market is so far maintained at this level, but business is dull. **Guaiacol Carbonate,** about 8s. 3d. per lb.; the market is unchanged, with very little doing. **Hexamine,** about 3s. 10d. per lb.; spot parcels are offering at this rate; Continental offers seem to vary. **Hydroquinone,** about 3s. 6d. per lb.; the demand for this product has not been so good this week. **Methyl Salicylate,** 2s. 5d. to 2s. 6d. per lb.; the market keeps well up to these figures, with demand poor. **Methyl Sulphonal,** about 15s. per lb.; there appears to be no interest in offers at about this figure. **Paraformaldehyde,** 3s. 9d. to 3s. 11d. per lb.; slightly easier rates are being quoted on a dull market. **Paraldehyde,** about 1s. 5d. per lb.; offers seem plentiful, with business very limited. **Phenacetin,** about 6s. 3d. to 6s. 6d. per lb.; the market holds fairly well at these figures, despite the lack of business. **Phenazone,** about 7s. 3d. to 7s. 6d. per lb.; no further falls in values are recorded, and market flat. **Phenolphthalein,** 6s. 6d. to 6s. 9d. per lb.; at these rates the market seems to be quite steady. **Piperazine,** about 4s. 6d. per oz., in kilo lots; the market remains very quiet; spot goods offering. **Potassium Bromide,** B.P., crystals and granular, 6½d. to 7d. per lb.; the demand for the spot goods on offer continues on the small side, and prices are not at all steady. **Potassium Permanganate,** B.P., 10d. to 10½d. per lb.; matters are not so brisk in this product, and prices as quoted seem steady. **Potassium Sulphoguaiacolate,** about 5s. 6d. per lb.; no further fall in quoted values is recorded, with market flat. **Salol,** 2s. 8d. to 2s. 9d. per lb.; offers are being made at these rates, with little buying taking place. **Sodium Benzoate,** about 2s. 6d. per lb.; nominal; no life in the market. **Sodium Bromide,** B.P., crystals and granular, 7d. to 7½d. per lb.; this product is still in good supply on spot, with little moving off, and prices are rather weak. **Sodium Diethylbarbiturate,** about 18s. 6d. per lb.; the market is maintained at last week's cheaper level, but business is lacking. **Sodium Salicylate,** powder 2s. 4d. per lb., crystals 2s. 6d. to 2s. 8d., phys. pure flake 2s. 10d. per lb.;

the spot position keeps very steady at these rates, and Continental rates are much dearer **Sulphonal,** about 14s. 6d. per lb., nominal; the market has been inactive. **Terpin Hydrate,** about 1s. 9d. per lb.; spot offers are being made at about this figure, but very little business has been on the market. **Thymol,** about 15s. per lb.; quoted at this level with not much doing.

Coal-tar Products, Intermediates, Etc.—Like the other markets, this section has experienced a poor week of business, and the only alterations in prices have been in buyers' favour. **Aniline Oil,** about 9d. to 9¼d. per lb., drums free; this market is steadier after the drop in price recorded last week. **Aniline Salt,** 9½d. to 10d. per lb., casks free; the market keeps steady but quiet at these levels. **Betanaphthol,** 1s. 1d. to 1s. 2d. per lb.; very little business is reported; quoted rates are unchanged. **Benzol,** 1s. 4d. per gallon, f.o.r., makers' works, in buyers' packages; a considerable reduction has been made here, but business still hangs. **Toluol,** 1s. 9d. per gallon, f.o.r., makers' works, in buyers' packages; with benzol this product has dropped threepence a gallon during the week; this change was not unexpected. **Xylol,** pure 2s. 3d., commercial 1s. 6d. per gallon, drums extra; quoted rates are unchanged on a flat market. **Naphtha,** about 1s. 5d. per gallon; things are still very sluggish here, and prices as quoted are none too steady. **Solvent Naphtha,** 90/160, 1s. 5d. per gallon, drums extra; business still poor, and market unsteady and tends to weaken. **Heavy Solvent Naphtha,** 90/190, 1s. 4d. per gallon, drums extra; the tone is unsteady, with a tendency to slightly easier rates. **Special Oil,** for Diesel and motors, 10d. per gallon, barrels free; dealers are quoting at unchanged rates on a dull market. **Burning Oil,** crude, No. 3 8½d., No. 2 8d. per gallon, barrels free; prices are unchanged on the week, with business very dull. **Creosote Oil,** 10d. per gallon, in bulk supply, f.o.b.; dealers' prices are unaltered on the week; very little doing. **Carbolic Acid,** crystals, about 1s. 2d. per lb., f.o.b.; some inquiry continues, but actual business is small; at this rate the market seems steady enough. **Naphthalene,** £20. per ton; the demand is slow; quoted rates are steady; crude £7. to £13., crystals £21., powder about £17., balls £24, tablets £28., candles £28. per ton, packages free. **Disinfectants,** 3s. 9d. per gallon, barrels free; a fair inquiry has been received, and prices seem steady. **Pyridine,** 19s. per gallon; at this higher price the spot position appears to be very firm. **Hexamethylene,** 4s. to 4s. 3d. per gallon; these rates govern a very steady market. **Pure Methyl Alcohol,** £100. per ton, ex wharf, London; at this price the spot position keeps very steady, but business has been limited. **Pitch,** about 135s. per ton, in London; there is no change in this market to record; business, so far as spot is concerned, is very little.

SWANSEA MARKET REPORT. Wednesday.

There was no alteration in quotations for **Tinplates,** the market being quiet at £1. 3s. 1½d. per standard box. **Galvanised Sheets** had an improved tone, with larger turnover, on the basis of £17. 12s. 6d. per ton f.o.b. **Copper,** firmer, with prices slightly higher, at £65. 5s. 9d. per ton prompt, and £66. 2s. 6d. three months. **Tin,** irregular, prompt £184. 7s. 6d., and three months £185. 7s. 6d. **Lead,** firmer, at £24. 7s. 6d. per ton prompt, and forward £24. 10s. for foreign; English £25. 12s. 6d. **Spelter** ruled firm at £31. 12s. 6d. per ton prompt, and £31. 15s. three months. **Zinc Sheets,** dearer, at £39. 7s. 6d. per ton. **Sulphate of Ammonia,** dull, at £14. 15s. to £13. 12s. per ton. **Sulphate of Copper,** quiet, £26. 7s. 6d. per ton, less 5%. **Nitrate of Soda,** dull, with prompt at £13. 12s. 6d. per ton. **Bonemeal,** in little demand, with Indian, prompt, at £8. 17s. 6d. per ton. **Oxalic Acid,** in poor demand and cheaper, at 6¼d. per lb. on rail. **Pitch,** steady, at £6. 12s. 6d. per ton ex ship. **Arsenic** remains dull, with small supplies of Cornish; white powdered at £71. 12s. 6d. per ton, f.o.b. **Turpentine,** quiet, with American, prompt, at £3. 17s. 3d. per cwt. **Copperas** remains dull, at £2. per ton, delivered. There is a fairly brisk demand for **Coals** of all descriptions; steam qualities are being well shipped, with best Admiralty smokeless £1. 10s., seconds £1. 8s. 6d., ordinaries £1. 7s. 6d., Monmouthshire black vein £1 8s per ton, all f.o.b. **Anthracite** in fair demand, with unchanged quotations. **Patent Fuel,** quiet, with no alteration. **Cokes,** firm; export £2. 14s. 9d. per ton, f.o.b., foundry £2., and furnace £1 10s. per ton on rails at ovens

LONDON METAL MARKET. Wednesday.

Copper: Standard brands, £64. 17s. 6d. to £65., cash; £65. 12s. 6d. to £65. 15s., three months; electrolytic, £72. to £72. 10s. **Tin**: Standard, £183. 15s. to £184. cash; £184. 15s. to £185., three months; Straits, £187. 5s.; English, £184. 10s. **Lead,** soft foreign, £24. 7s. 6d., prompt; English, £25. 10s.; chemical sheet, 33s. per cwt. for 2-ton lots, delivered. **Spelter,** prompt, £31. 7s. 6d.; hard £25. 5s. **Antimony,** English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35. **Aluminium,** 98—99%, £115. to £120.; foreign, £110. c.i.f. **Nickel,** £130., delivered; £125. to £130. for export, f.o.b. **Mercury,** £10. **Bismuth,** 10s. **Platinum,** 500s. per oz. **Wolfram,** spot, 13s. per unit, c.i.f., United Kingdom or Continent. **Zinc Dust,** quotations are as follows: Highest grade English, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET. Wednesday.

There is no improvement to report in the demand for heavy chemicals, and values generally continue in buyers' favour. For **Alkali** products prices are maintained at recent rates, and makers' output is fairly well engaged. Some cheap supplies of **Caustic Soda** and **Bleach** are offered from the Continent. **Chlorates** and **Bichromates** are quiet and unchanged at recent rates. There is a steady export demand for **Saltcake,** but the home trade is quiet at £4. 10s. per ton, carriage paid. **Sulphate of Copper** only moves off slowly, and price nominal, at £26., f.o.b. **American Sulphur,** firm, at £5. 5s. on rails. **Phosphate** and **Hyposulphite of Soda** are in small request and values easy. **Nitrite of Soda,** steady, at £26. 10s., basis 100%, ex store. Concentrated **Sodium Sulphide,** 60/62%, dull, at £15. per ton. White powdered **Arsenic,** firm, at £70. on rails, Cornish works. Yellow **Prussiate of Potash,** dull, at 1s. 2½d. per lb. **Soda,** lower, at 6½d. per lb. **Carbonate** and **Caustic Potash** are in short supply and values maintained. **Acetic Acid** and **Acetate of Soda,** firm, and supplies short. **Formaldehyde,** 40%, scarce, and price higher, at £98. per ton. Grey and brown **Acetate of Lime,** unchanged in position. **Lead Salts** have an upward tendency; white **Acetate,** £41.; brown, £43.; and **Nitrate,** £43., delivered. **Barium Chloride,** dull, at £15. per ton. **Copperas** is in good request. **Oxalic Acid,** slow of sale, at 6d. per lb. **Permanganate of Potash,** 9¾d. per lb.

LIVERPOOL CHEMICAL MARKET. Wednesday.

A steady business, though on a moderate scale, continues to be done in the heavier chemicals on home-trade account. The industrial situation is more settled, and conditions for manufacturers are somewhat easier, so that an improvement in trade is looked for. This, if occurring, will mean a larger consumption of chemicals. In the export branch, shipments have gone on more briskly. **Bleaching Powder** has been in fair demand, and is £10. to £11. per ton for use in the United Kingdom, and £11. per ton for export. **Calcium Chloride** has been more inquired for, and is £5. 17s. 6d. per ton. **Caustic Soda** continues in quietly steady demand on home-trade account and has been shipped freely on export account; it is £20. 7s. 6d. to £21. 7s. 6d. per ton for 76%, carriage paid, for use in the U.K., and £20. 10s. per ton for export. **Bicarbonate of Soda** has been in fair request for home-trade uses and has had an active shipment for export; it is £10. 10s. per ton, carriage paid, for use in the U.K. **Soda Crystals** have been in quietly steady demand and are £5. 5s. per ton for home-trade uses. **Nitrate of Soda** has had a moderate sale, and is £13. 5s. to £13. 10s. per ton. **Borax** has been rather more in request; commercial crystals are £27. per ton, and powdered £28.; higher grades are, crystals £31. per ton and powdered £32. per ton, carriage paid in the U.K. **Saltcake** has had a fair sale, and is £4. 10s. to £5. per ton for the home trade, and £5. to £6. per ton for export. **Bichromate of Soda** has been quiet, and is 4½d. per lb., c.i.f. to usual ports. **Ammonia Alkali** has sold with some freedom for use in the U.K., and has again been in good demand for export; the price is £7. 12s. 6d. per ton for home-trade uses, and £8. per ton for export. **Hyposulphite**

of Soda continues in very fair request, and is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial, and £15. to £16. per ton, in 1cwt. kegs, for photographic. **Sulphide of Soda** has had a slow sale; solid is £16. per ton, and crystals £10. 10s. to £11. per ton. **Chlorate of Soda** continues quiet, and is 3d. to 3¼d. per lb. **Phosphates of Soda** has been inactive, and is £15. to £15. 10s. per ton. **Prussiate of Soda** has been in moderate demand, and is 7d. to 7½d. per lb. **Yellow Prussiate of Potash** has been in quietly steady demand, and is 1s. 3d. to 1s. 3¼d. per lb. **Red Prussiate** has been rather more in request, and is 3s. 3d. to 3s. 6d. per lb. **Carbonate of Potash** has sold more readily, and is £25. to £32. per ton., according to quality. **Nitrate of Potash** has been in fair demand, and is £33. to £35. per ton for refined. **Chlorate of Potash** has been very quiet, and is 4d. to 4¼d. per lb. **Caustic Potash** has had a somewhat freer inquiry, and is £32. to £33. per ton. **Permanganate of Potash** has been rather more in request; it is 10d. to 10½d. per lb. **Bichromate of Potash** has been quieter, and is 5¾d. per lb., c.i.f. to usual ports. **Salammoniac** has been in quietly steady demand; first quality is £63. per ton, second quality £60., and third £57. **Sulphate of Ammonia** has had a very limited inquiry for use in the U.K., but has had a fair shipment on export account; neutral is £14. 15s. per ton, and ordinary £13. 12s. per ton, to the end of August. **Carbonate of Ammonia** has been steadily called for, and is 4d. per lb. **Muriate of Ammonia** has been rather more in request, and is £32. to £33. per ton. **Magnesia** has sold with some freedom; **Carbonate** is £2. 5s. per cwt., and **Sulphate** £5. to £6. per ton. **Alum** has had a moderate inquiry, and is £12. per ton for the home trade, and £11. 10s. to £12. per ton for export. **Sulphate of Alumina** has been rather more in request, and is £8. to £11. per ton, according to quality. **Sulphur** has again been in very fair demand; flowers are £10. per ton, roll is £8. 10s. per ton, rock £8. to £8. 10s. per ton, and American £5. to £5. 10s. per ton. **Tartaric Acid** has sold rather freely, and is 1s. 3d. to 1s. 3½d. per lb. **Cream of Tartar** has been steadily called for, and is £4. 12s. to £4. 15s. per cwt. **Boric Acid** has been quieter; commercial crystals are £52. per ton, and powdered £58., £2. per ton more being charged if in casks. **Citric Acid** has sold more readily, and is 1s. 9d. to 1s. 10d. per lb. **Oxalic Acid** has been inactive, and is 6¼d. to 6½d. per lb. **White Acetate of Lead** has had a moderate inquiry, and is £42. to £43. per ton. **Sulphate of Copper** has been quiet both on export account and for the home trade; it is £26. to £26. 5s. per ton, less 5%, in casks, f.o.b. at Liverpool. **Arsenic** has been but little called for; white powdered is £72. per ton.

WEST OF SCOTLAND CHEMICALS. Wednesday.

The demand for chemicals on home-trade account has been rather restricted on account of the holidays. Export inquiries also continue to be limited. Prices are easier in certain lines, but otherwise nominal quotations still hold steady. The following prices are at Glasgow, unless otherwise stated:—**Alum,** little doing, and in small demand; prices have been reduced and now stand at £12. 5s. for lump, and ground £12. per ton. **Arsenic** continues in short request, and supplies are still very scarce; it is quoted on spot at £77. net. **Barium Chloride** remains very quiet, despite the recent reduction to £15. per ton. **Bleaching Powder** does not show much movement, and the quotation still stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax,** granulated, is on offer at £26. 10s. per ton net, in 2cwt. bags. **Calcium Chloride,** 70—75 per cent. solid, £5. 12s. 6d. per ton. **Citric Acid** is a declining market, with the price reduced to 1s. 7½d. per lb., less 5%. **Cupper Sulphate** is but little in request at last week's figure of £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar,** easier, with better inquiry, at £4. 8s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in quieter demand; brown steady at £40. 10s. per ton, net, and white better at £40. 10s. per ton, net. The market for **Magnesium Chloride** is slow, with quiet business at £3. for spot. **Oxalic Acid** at 6¼d. per lb. **Paraffin Wax** experiences a fair export trade at 2¾d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull at the rather easier figure at 1s. 4d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1. 11s. per ton, but business is nominal. **Sodium Bichromate** remains steady, with business on the basis of 4½d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2cwt. bags; and £11. 10s. in 1cwt. kegs. **Tartar Emetic,** 43—44%, in fair request at 1s. 1½d. **Tartaric Acid** still shows a quieter tendency at 1s. 2¾d. per lb.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	**19s. 6d.**	**24s.**
Half-yearly (26 numbers)	**10s. 6d.**	**13s.**
Quarterly (13 numbers)	**5s. 6d.**	**7s.**

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."

Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

"TOLERANCES" ON CHEMICAL SPECIFICATIONS.

In the disputes which arise occasionally between the sellers and buyers of metallurgical products in transactions conducted upon a specification basis, the cause of disagreement is very often to be found in the interpretation of the chemical specification. The limits specified are frequently so fixed and narrow that it is not always practicable to keep within the border line, and difficulties arise from time to time through small differences between chemists' results. Analytical chemistry is a very exact science, and it is this very accuracy that has led to the stringency with which chemical specifications are drawn up, but it must not be overlooked that even qualified chemists working by identical methods on samples of the same material are liable to obtain differences in results, very slight in themselves, but at times large enough to put the material outside the limits of a given specification. That such differences in results do exist, and cannot, so far as may be judged, be obviated, has been definitely confirmed by the experience of the British Chemical Standards Movement. The organisers and committee of this movement have had prepared a number of standard samples of irons and steels and of basic slag, for the use of chemists in checking the accuracy of their methods. The compositions of the various standards, particulars of which, as they have been made available, have appeared in our columns from time to time, were in all cases checked by a large number of independent analysts. The figures obtained represent hundreds of carefully conducted estimations, and indicate conclusively that identity in the analytical figures cannot be obtained, although the amount of divergence above and below the average is approximately constant. Figures showing differences in analytical results found by the United States Bureau of Standards, and those recognised by the Iron and Steel Institute and National Physical Laboratory substantially confirm those occurring in the case of the above standards. At the annual meeting of the co-operators in the British Chemical Standards Movement, which was held at York in February, a resolution in which it was considered that the rejection of steel and cast iron is not warranted on chemical analysis alone, and in which it was requested that a list of limits or tolerances in analytical figures should be established, was carried unanimously. Acting on this resolution the committee have now prepared a pamphlet in which the

whole matter is reviewed and the suggested tolerances for sulphur, phosphorus, silicon, carbon, and manganese in the analysis of irons and steels are given. It is pointed out, for example, that in the case of a sulphur determination on a specification not to exceed a total of 0.03 per cent., figures varying between 0.030 and 0.038 per cent. may be obtained by chemists of equal status working by identical methods. Expressed briefly, the method proposed for determining the amount of tolerance is by fixing upon the average of a large number of analyses and allowing half the range of the divergence in the figures obtained as the amount of permitted tolerance on either side of the average. The pamphlet is at present being circulated amongst the co-operators and other persons interested, for the expression of their views. We ourselves are of the decided opinion that the introduction of a tolerance system on the lines and magnitude suggested would be wise and would eliminate much of the friction occurring between analysts and buyers and sellers of metallurgical products without in any way detracting from the value of the chemical specification as a guarantee of quality.

CHEMICAL PLANT MANUFACTURERS' GRIEVANCES.

It seems to be a legitimate inference from the chairman's speech at the recent annual general meeting of the British Chemical Plant Manufacturers' Association, that the relations between this body and the Association of British Chemical Manufacturers are not so closely knit as generally believed. It is, for example, somewhat surprising to learn that the B.C.P.M.A. is to take no part in the Chemical Section of next year's British Empire Exhibition, a section that, according to Sir Max Muspratt's statement a few weeks ago, is to be unique in its comprehensiveness, "a complete survey of Great Britain's services to chemistry, from top to bottom." Seeing that the B.C.P.M.A. is affiliated with the Association of British Chemical Manufacturers, this state of affairs is rather difficult to explain, especially in view of the fact that the plant manufacturers' conjoint exhibit at the last British Industries Fair aroused widespread interest and was universally judged a success. It may be deduced from Mr. Fraser's speech that the members of the B.C.P.M.A. themselves were desirous of securing representation in the Chemical Section, and elucidation of the whole position will be welcomed. With regard to the disappointment expressed by Mr. Fraser on the half-hearted way in which standardised chemical plant has been received by chemical manufacturers, or, rather, on the paucity of the demand for such plant up to the present, and his statement to the effect that he would take the matter up again with the A.B.C.M., it would be absurd to suppose that the A.B.C.M. could or should exert any form of compulsion upon its members to use the standardised jacketted pans or filter presses, but Mr. Fraser's grievance appears to be that the members are not encouraged to use such plant to the extent that the co-operation of the A.B.C.M., when the specifications were being drawn up, led the plant manufacturers to expect.

A REASONABLE REQUEST.

On another page we print a copy of the memorandum that has been forwarded by the British Chemical and Dyestuffs Traders' Association to the Treasury and Customs authorities in which it is suggested that modifications might profitably be made in the method of payment of duty under Part I. of the Safeguarding of Industries Act. From the merchants' point of view the advantages resulting from a system allowing imported goods liable to the 33⅓ per cent. duty to be bonded are obvious, and are well set out by the Association in their memorandum. Goods destined for home consumption will have to pay the duty in any case, and it was never the intention of the framers of the Safeguarding Act that chemicals to be re-exported should pay the import duty. On the latter point especially the case put forward by the Association is exceptionally strong, and it is difficult to see how the Treasury and Customs can refuse logically to meet the merchants' request. The chaotic condition of the international exchanges has reduced the real value of Part I. of the Safeguarding of Industries Act very considerably, and we cannot see how what little value it does at present possess will be jeopardised in any way by the introduction of a bonded warehouse system for the payment of the duty. On the other hand, it is, unfortunately, only too true that under the present conditions much of our *entrepôt* trade in chemicals has been lost, and with it also considerable business for chemicals that are made here, but it cannot be doubted that the proposals set out in the memorandum will, if accepted, lead to an immediate and material increase in the shipment of chemicals from this country.

BRITISH TRADE WITH GERMANY.

A summary statement of the value of trade between the United Kingdom and Germany during the first six months of 1923 has just been issued by the Board of Trade, and in view of the trend of both political and economic events in the latter country, a special interest is lent to the statement. On the whole, the trade of the period under consideration compares better than might have been expected with that of the first half of 1922, although it should be borne in mind that the economic disturbances arising out of the occupation of the Ruhr affected the trade of only a part of the six months. Expressed in values, the total imports from Germany during January to June, 1923, were £16,930,000., the exports of U.K. products to Germany were £20,854,000., and the re-exports of foreign and colonial merchandise from the U.K. to Germany were £10,391,000. For the first half of 1922 the corresponding figures were £26,524,000., £32,075,000., and £16,985,000. The principal features to be noted are the heavy increase in our exports to Germany of coal and coke, of pig iron, and iron and steel plates (except tinned plates), and a considerable falling off in the rate of exportation of most textile products. Imports of dyestuffs from Germany were valued at £270,000., against £505,000. in the first half of 1922; and of general chemicals at £848,000., as against £1,485,000.

THE CELLULOSE ACETATES.

RECENT PROGRESS IN CHEMISTRY AND TECHNOLOGY.

By "Investigator."

FIRST prepared by Schutzenberger in 1865, cellulose acetate remained more or less of a chemical curiosity until a process for its manufacture, by the action of acetyl chloride and zinc acetate on cellulose, was patented by Cross in 1894. In the intervening period, the use of sulphuric acid and other reagents as acetylation catalysts, together with the introduction of less drastic methods of acetylation, had led to the production of a less degraded and technically more valuable material.

In 1905, Miles in the United States, introduced the process of regulated hydrolysis or "ripening," by which the acetate became soluble in acetone, thus making feasible the use of a comparatively cheap and non-toxic solvent. The use of cellulose acetate as the basis of aeroplane-wing tautening compositions ("dopes") lacquers, non-flaming celluloid and allied materials, has called forth a host of patents covering the use of all classes of compounds as solvents and softeners ("camphor substitutes.") Recently there has been a great development of cellulose acetate artificial silk, first patented by Lederer in 1906, in competition with nitrate and viscose silks. Attempts to carry out the acetylation without acetic anhydride and so to cheapen the process have not met with much success.

The Partial Hydration or "Ripening" Process.

Acetates prepared from unmodified cellulose by acetylation with acetic anhydride and acetic acid in the presence of sulphuric acid—that is primary acetates—are practically non-hydrated triacetates, soluble in chloroform and some other chlorhydrocarbons, but only partially soluble in acetone. Miles found that, by heating this primary acetate with small quantities of water (partial hydration or "ripening"), it became soluble in acetone but insoluble in chloroform. Similar conversions to secondary acetates can be effected by treating the primary acetate with alkali (partial saponification), by adding alcohol to the acetylation bath, and according to H. Dreyfus, by heating with acetic acid in the absence of anhydride ("depolymerisation.") The latter prepares an acetate giving solutions of high viscosity, by controlling this "depolymerisation" process so as to obtain a product insoluble in chloroform, soluble in chloroform—alcohol, and in acetone. Thus, primary acetate syrups, after neutralising the sulphuric acid, give secondary acetates of good quality, completely soluble in acetone, by heating with a little water at 98° C. for from 24 to 96 hours. A primary acetate itself can be "ripened" by heating with 95 per cent. acetic acid, alone, or in the presence of sodium bisulphate, or by heating with aniline or phenol containing a little water. During the "ripening" process there is a slight drop in the acetyl value, but the viscosity in solution is maintained and the percentage of the deleterious combined sulphuric acid falls.

Acetylation Catalysts.

Of the large number of catalysts proposed—*e.g.*, phosphoric acid, bromine (that is bromacetic acids), zinc chloride, chlorides and oxychlorides of sulphur and phosphorus, dimethyl sulphate, chloracetic acids, the large majority are dehydrating agents, as in the case of esterifications in general. Others, such as methylamine sulphate, give rise to sulphuric acid in use. According to Ost (*Zeit. angew, Chem.*, 1919), acetylation with sulphuric acid is much more rapid than with zinc chloride. Thus, whereas a mixture of 10 parts cellulose, 45 parts acetic anhydride, 45 parts glacial acetic acid, takes several weeks to acetylate at ordinary temperatures in the presence of 5—10 per cent. of fused zinc chloride, a similar mixture will acetylate in a few hours at 35°-40° C. in the presence of 1-2 per cent. of sulphuric acid. Even with these small proportions of catalyst, however, the primary acetate still contains combined sulphuric acid. The Bayer Company acetylate in the presence of 15 per cent. sulphuric acid at low temperatures. After one day, the primary acetate retained more than 3 per cent. of this acid, but on allowing the syrups to ripen for 4 days at 25° C., this fell to 0.17 per cent., the combined acetic acid falling from 57.4 to 50.9 per cent. during the same period. The Usines du Rhône use 3 to 5 per cent. sulphuric acid and operate at about 28° C. to obtain a primary acetate (*Brit. Pat.* 146,092, of 1920).

With sulphuric acid there is a tendency for the product to char and to hydrolyse, giving rise to discoloured solutions and brittle films. The formation of aceto-sulphates is also a difficulty, as their presence affects the stability of the finished acetate. Sulphuryl chloride offers a distinct improvement over the acid, especially if the catalyst is formed *in situ* from chlorine and sulphur dioxide gases (Barnett, *J. Soc. Chem. Ind.*, 1921). Acetylation proceeds very rapidly and smoothly with good yields, the resulting solutions being quite bright and clear, while the finished products are readily soluble in a variety of solvents. The composition of the product varies with the temperature and with the ratio of SO_2 to chlorine used, a large excess of the latter giving mainly diacetate at temperatures below 65° C., while with nearly equal amounts, a triacetate product results, especially if the temperature exceeds 65° C. The enhanced activity of the catalyst, formed *in situ*, over sulphuryl chloride added as such, is attributed to its nascent condition. In the same way, Zdanowich (*Brit. Pat.* 139,232, of 1918), makes use of chloracetic acid prepared *in situ* as an initial, non-degrading catalyst, and completes the acetylation with small amounts of sulphuric acid. High viscosity acetates, soluble in both chloroform and acetone, are claimed. The syrup resulting from acetylation can be coagulated directly to form the so-called "acetose" silk, after filtering and freeing from air bubbles.

Cellulose Acetate from Wood Pulp.

Starting with sulphite pulp, an acetate product can be made by digesting a mixture of the bleached pulp (1 part), glacial acetic acid (2.8 parts), acetic anhydride (4 parts) and zinc chloride (0.2 part), for about 8 hours at 65° C. (*Brit. Pat.* 130,029, of 1917).

Some processes operate so as to prevent the acetate from going into solution, as in cellulose-nitrate manufacture, a more uniform product, at less cost, resulting. Thus, acetylation is carried through with acetic anhydride alone, or in the presence of non-solvents such as benzene and petroleum hydrocarbons (*U.S. Pats.* 1,263,119 and 1,265,216, of 1918). To induce reactivity, various methods of pre-treating the raw material have been proposed, such as preliminary treatment with acetic acid (*German Pat.* 299,181, of 1914), alcohol and acetic acid (*U.S. Pat.* 1,265,216, of 1918), alcohol and benzene (*U.S. Pat.* 1,338,661, of 1920), chlorinated acetic acid (*U.S. Pat.* 1,330,543, of 1920), and alkaline hydrogen peroxide (*U.S. Pat.* 1,379,699, of 1921). In other processes, acetylation is carried out after slightly nitrating the raw cellulose by short treatment with a mixture of nitric acid and nitrobenzene (*Brit. Pat.* 145,524, of 1920). A noteworthy procedure is that of intensive mechanical disintegration of the cellulose, before acetylation, in the colloid mill of Plauson, the cellulose gel with particles 0.8μ in diameter which results, being readily esterified (*Brit. Pat.* 183,908, of 1921).

The Cellulose Acetate Complex.

Some idea of the extent of the degradation of the original complex in cellulose acetate, can be obtained by utilising the reducing action on Fehling's solution (the so-called "copper number.") With the same object, Barnett (*J. Soc. Chem. Ind.*, 1921), has prepared phenyl hydrazones and p-bromphenyl hydrazones from solutions of acetates in a variety of solvents. These hydrazones have definite melting points, are amorphous and are somewhat soluble in hot alcohol. It is possible to obtain identical compounds from different acetate preparations using various methods of precipitation. Assuming that each triacetate complex $[C_6H_7O_5(CH_3CO)_3]_n$, contains one ketone group, the relative complexity under different conditions can be gauged by estimating nitrogen or bromine in the various hydrazones. Thus, with triacetates, values of "$_n$" from 2 to 12 were obtained, according to the original cellulose used, the solvent and the time of heating with the reagent. The most complex hydrazone ($_n$ = 12), was given by a triacetate prepared from cotton-wool, after 10 hours at the boiling point in phenol. With the bromine compound, values of "$_n$" from 7 to 36 were obtained, indicating much less degradation of the cellulose acetate by this reagent. In this case, too, phenol gave the largest molecule.

Transition from Non-Solvent to Solvent.

The chaotic situation in this field has been somewhat relieved by the systematic study of solvents for aeronautical purposes (*Aeronautical Advisory Committee, Reports and Memoranda*, 568). Nevertheless, claims continue to be put forward for many compounds without solvent action. With

cellulose acetate there is a more or less sharp transition from solvent to non-solvent, that is, on cooling a weak solution, the temperature of precipitation ("transition temperature"), is only one or two degrees lower than with a concentrated solution. Also, the volume of non-solvent necessary to begin the precipitation is practically independent of the concentration of the solution. This transition point varies with the make of acetate. Thus, in benzyl alcohol, it is 25° C. for a French acetate, 25.5° to 28.5° C. for British esters, and 40° C. for an American material. Some other values are as follow, a French variety being used:—Ethyl formate —10°, phenyl acetate, 32° C., triacetin below 0° C., methyl lactate below 0° C., methyl alcohol (under pressure) 80° C., chloroform (under pressure) 85° C., methyl ethyl ketone (under pressure) 90° C., ethyl alcohol (under pressure) 120° C., nitrobenzene 98° C., and cyclohexanol 79° C.

In the presence of certain substances, a liquid becomes a solvent at a lower temperature. In the same way, the resistance to precipitation by added non-solvents is increased; for example, water up to 6 per cent. increases the solvent power of acetone. Whereas pure methyl-ethyl ketone is practically a non-solvent below 90° C., the industrial product is a solvent at ordinary temperatures. A similar effect is observed with ethyl alcohol which, in the presence of 15 per cent. of water, will dissolve the ester at 60° C., while impure benzyl alcohol will dissolve it at a lower temperature than the pure material.

This behaviour is very pronounced with binary mixtures. Thus, chloroform becomes a solvent on addition of alcohol. Although nitro-xylol is a non-solvent at moderate temperatures (below 160° C.), the mixture with benzyl alcohol is a solvent (above —10° C.). A similar behaviour is noticed with ethyl acetate-benzyl alcohol mixtures. A mixture of ethyl acetate (80 parts) and alcohol (20 parts) both ordinarily non-solvents, becomes a solvent above 40° C., a behaviour common to binary mixtures of esters and alcohols, including water.

Solvents for Cellulose Acetate.

In many of the homologous series, there is a rapid fall in solvent power with increase in molecular weight and complexity, the first member, as is usual with other properties, being somewhat anomalous. For instance, in the formic ester series, methyl formate has a transition point of —150° C., ethyl formate —10° C., while butyl and amyl formates are solvents only in admixture with alcohol. A similar drop in solvent properties is observed in the series of aliphatic and aromatic alcohols, the values for methyl, ethyl and butyl alcohols being 80°, 120°, and 150° C., and for benzyl, tolyl, and cumyl alcohols 25°, 50° and 60° C. respectively. According to Fenton and Berry, there appears to be a relation between the dielectric constant and the solvent power (*Proc. Camb. Phil. Soc.*, 1920).

Hydrocarbons—*e.g.*, benzene and naphthalene, are non-solvents, in which connection it is noteworthy that an acetate-naphthalene composition, consisting of acetylcellulose (75 parts), naphthalene (25) and acetone (60 parts), is the subject of a recent patent. Benzene gelatinises, but does not dissolve, the ester. With chlor-hydrocarbons, the solvent power diminishes with increase in chlorine content. Thus, chloroform and tetrachlorethane are solvents with alcohol, while carbon tetrachloride is a non-solvent even with alcohol. The use of methylene chloride (b.pt. 41° C.) has been patented recently (*U.S. Pat.* 1,384,188, of 1921). The chlornaphthalenes alone are non-solvents. Nevertheless, a recent patent proposes to employ them in this connection.

Among the esters, the simpler formates and acetates are useful solvents, especially with alcohol, many being good substitutes for acetone. Phenyl, benzyl and tolyl acetates constitute good solvents in alcohol mixture; acetoacetic ester, ethyl tartrate and triacetin dissolve the acetate below 0° C., but higher esters, such as methyl oleate and fatty oils, are non-solvents. In this group, ethyl propionate, phenyl salicylate, resorcinol monoacetate (m.pt. 50° C.), the neutral tartrates and citrates of *n*-butyl, isobutyl, and isoamyl alcohols, and the neutral esters of adipic and other polybasic acids, have all figured in recent patent literature.

In the group of ethers, the members are non-solvents, but appear to have a gelatinising action. The Bayer Company claim the use of β-naphthyl amyl ether as a cellulose ester "softener," stable to light (*German Pat.* 307,125, of 1917). Aromatic nitro compounds and amines, alone or with alcohol, are generally solvents below 50° C.; aldehydes of fairly simple constitution, such as acetaldehyde (*Brit. Pat.* 131,647, of 1918), benzaldehyde and furfurol (*Brit. Pat.* 138,078, of 1920) dissolve the ester at ordinary temperatures, but oenanthaldehyde, $C_6H_{13}CHO$, is a non-solvent. Among ketones, a similar rule applies. Thus, camphor, molten or in solution, will dissolve the acetate, while no less than three patents have been granted, covering the use of cyclohexanone and its homologues. Di-alkyl sulphones are claimed as solvents by the Kodak Company of America. Generally speaking, aromatic hydroxy compounds are serviceable solvents—*e.g.* benzyl alcohol, phenols, naphthols, and eugenol. Terpineol, however, is a non-solvent. The American Dupont Company have recently patented the use of a mixture of *o*- and *p*-hydroxybenzyl alcohols. A new low boiling-point solvent is methyl cyanide (b.pt. 82° C.), prepared from acetylene and ammonia (*German Pat.* 368,476, of 1918).

Acetyl Aeroplane Dopes.

These are solutions of cellulose acetate in a mixture of low and high boiling-point solvents used for tautening and weather-proofing the linen fabric composing the wing surfaces. Owing to the slow rate of burning of the film, acetyl dopes have largely replaced those with a nitro-cellulose basis. A typical three-coat formula would be, cellulose acetate 8.5 parts by weight, acetone 50, alcohol 24, benzol 24, benzyl alcohol 2 parts by volume, and triphenyl phosphate 1.5 parts by weight, the latter serving to render the film less hygroscopic. A dope solvent of this composition will dissolve cellulose acetate at temperatures above —50° C. The simpler formic and acetic esters can replace acetone, the effect of organic acids on the tensile strength of the fabric being slight. In fact, acetic and formic acid dopes have been proposed, but practical difficulties would be encountered, especially with regard to hand-brushing.

Huebner proposes to use an emulsion consisting of cellulose acetate, acetic acid and water, stabilised by sulphonated castor oil (*Brit. Pat.* 127,027, of 1917). Such a mixture would permit of the use of water-soluble fireproofing agents. In this connection, the production of stable suspensions of acetate in water and other non-solvents by treatment in the colloid mill of Plauson, is noteworthy. By pigmenting the dope with ochre, iron oxide, zinc white, carbon black, and aluminium powder, it has been found possible to dispense with the coating of protective varnish previously necessary. Ester dopes, especially if pigmented with zinc white, tend to lose in viscosity on standing, but this thinning process can be retarded by adding a trace of tartaric or citric acids (*Brit. Pat.* 125,033, of 1917). By the addition of "borated benzol" (10 per cent. boric acid), it is claimed that triphenyl phosphate can be dispensed with, and that more non-solvent can be employed in the dope formula (*Brit. Pat.* 131,082, of 1918). To reduce the rate of water absorption, drying oils and the glycol esters of non-drying-oil fatty acids can be incorporated, the latter being more resistant to cold than the oils themselves (*German Pat.* 338,475, of 1918).

Serviceable softening agents should be good solvents alone or in presence of small amounts of the more volatile solvents. Dopes containing them should give translucent, flexible films, free from white patches and resistant to weathering. triacetin, alone and with acetanilide, lactic esters, and various liquid sulphonamides—*e.g.*, the mixed xylylene methyl ethyl sulphonamides (Dreyfus, *Brit. Pat.* 154,334, of 1919) have been used in place of benzyl alcohol.

Non-Inflammable Celluloid.

The non-flaming property of cellulose acetate has led to its use instead of celluloid, after incorporation with various "plastifiers." In sheet form ("cellon"), it has found some use for windows. Among recently suggested "plastifiers" are borneol and resorcinol monoacetate (m.pt. 50° C.), the latter enabling the celluloid to be moulded while hot. Some are materials of low inflammability, such as triphenyl phosphate, glycerol (3 per cent.), and trichlor-tertiary butyl alcohol (3 per cent.), made by condensing chloroform with acetone (*Brit. Pat.* 195,849, of 1922). To obtain uniform distribution, the ester may be kneaded with the "plastifier" to which has been added a small proportion of volatile non-solvent, such as methyl alcohol or benzene. H. Dreyfus subjects the "celluloid" to pressures exceeding two tons per square inch, in order to increase its resistance to weathering (*Brit. Pat.* 118,891, of 1917).

It is of interest to note that non-dimming glass can be made by immersion in an aqueous methyl-alcohol solution of cellulose acetate, and that the Société du Verre Triplex make a reinforced glass, by applying gelatin and cellulose acetate solution in successive layers.

Acetate Artificial Silk.

Artificial silk made from cellulose acetate should possess many valuable properties. Its high elasticity should make

it suitable for working up in high-speed looms, while its fineness, lustre, "handle" and heat-insulating properties should make it eminently suitable for articles of apparel. Compared with other forms of artificial silk, there is a much greater increase in weight on manufacture, in relation to the raw cellulose. It should prove of service in marine biological work, for after six months immersion in sea water there was no apparent mouldiness (Dorée, *Biochem. J.*, 1920). It is more resistant to water than cellulose, and absorbs much less of this than other "silks." Thus after "whizzing," acetyl silk held 35 per cent. of water on the dry weight, while viscose silk retained 90 per cent. The latter property coupled with the high elasticity of the wet fibres, should enable it better to endure the rigours of laundering. In the following table are given some comparative figures, calculated for threads of equal diameter, for dry and wet tensile strengths and percentage elasticities:—

	Tensile Strength.		Elasticity.	
	Dry.	Wet.	Dry. Per cent.	Wet. Per cent.
Degummed Italian silk	100	94	13·2	15·9
Cuprammonium silk	44	32	7·9	11·5
Viscose (3 samples)	45—38	25—17	3·0—2·8	2·2—2·0
Chardonnet (4 samples)	55—37	32—20	3·6—2·6	3·2—1·7
Acetyl silk	25	21	6·1	5·4

According to the British Cellulose and Chemical Manufacturing Company, an acetone solution of the acetate is coagulated by passing into a bath containing a "swelling agent" such as thiocyanates, acetic acid or zinc chloride, in order to impart greater strength and elasticity to the filament (*Brit. Pat.* 179,234, of 1922). The Badische Company coagulate a 4 per cent. solution of acetate in cyclohexanone, while Zdanowich prepares "acetose" silk directly from the acetate syrup, or after treatment with formaldehye.

The Dyeing of Acetate Silk.

A difficulty encountered in the commercial exploitation of acetyl silk has been that of dyeing it successfully. Owing to its ester character, it has little affinity for the direct cotton dyestuffs or for the large majority of acid dyestuffs. After swelling, however, by treatment with aqueous alcohol or with solutions of thiocyanates (5-25 per cent.), the reactivity is much improved. Thus, whereas with methylene blue, the untreated acetate was dyed to its maximum depth of shade in several months, the swollen material took only a few minutes. Acetyl silk exhibits considerable affinity for many basic dyes, especially in the presence of salts such as the chlorides of sodium, zinc and magnesium. Certain hydroxy-azo compounds such as Alizarine Yellow R (p-nitraniline azo salicylic acid), can also be used. Owing to its slight affinity for direct cotton colours, this silk is not stained by the "bleeding" of other dyed fabrics in contact with it. In order to enhance its reactivity towards these dyes, the material can be "surfaced" with a layer of regenerated cellulose. For this purpose, it is subjected to a process of partial saponification or de-acetylation with cold caustic soda (2-15 per cent.), or with readily hydrolysable salts. The process can be regulated by cooling, by the addition of alkali salts, such as the chlorides, acetates, silicates, borates and aluminates, or by coating the fibres with soap. In the last method, the threads are first passed into a soap solution and then treated with brine to precipitate the soap (*Brit. Pats.* 193,912 and 194,244, of 1921). With the less highly-acetylated materials, the alkali treatment is carried out at about 70° C. with weak solutions (0.1 per cent.). The extent of de-acetylation can be estimated by extracting the product with cuprammonium solution and with acetone, and by the exhaustion of the alkali.

Very recently, a special class of cellulose acetate colours, the Cellutyl Colours or Ionamines, have been worked out by Green and Saunders (*Brit. Pats.* 7,980, 23,543, 9,792 and 25,989, of 1922).* These are omega-sulphonic acids of amino compounds and have the general formula $XNR.CHR^1.SO_3H$, where X is a hydrocarbon nucleus and R and R^1 are hydrogen or alkyl groups. The colourless members of this group can be prepared by the action of aldehyde-bisulphite compounds on primary and secondary amines. They are readily hydrolysed in solution into amido compounds and aldehyde bisulphites or their decomposition products. Thus, the amido azo benzene compound $C_6H_5N_2.C_6H_4.NHCH_2SO_3H$, gives amidoazobenzene which is readily absorbed by the fibre, in which state it can be diazotised, coupled and developed to give a galaxy of hues and shades.

EXPLOSIVES IN FERTILISER PLANTS.

THE SAFE USE OF DYNAMITE.

In a recent issue of the du Pont *Magazine*, Mr. J. L. Dunn discusses the use of dynamite as an explosive in fertiliser plants. Although the detailed instructions he gives relate to the use of a special brand of the du Pont dynamite, yet the information is of so general an importance that it cannot fail to be of interest to British handlers of large quantities of fertilisers.

The following account of Mr. Dunn's article is abstracted from the *American Fertilizer*:

The use of dynamite for blasting down the hardened materials which go into the manufacture of commercial fertiliser is of comparatively recent origin. The safety and economy of this method, as proved by a few plants in which it has been in regular use, warrants it as a general practice where similar conditions and materials exist. Acid phosphate, potash and nitrate salts are stored in warehouses in bulk during the summer and autumn seasons. During this storage period they become fixed and hard. It is a slow and difficult process to dig down these mountains of solidified material by hand when the rush of the mixing season is on, and great quantities are required in the mixing machines to turn out the complete fertiliser.

Never to be Used with Ammonium Nitrate.

Fertiliser consisting, wholly or in part, of nitrate of ammonia, should never be blasted, for the reason that nitrate of ammonia itself is an explosive and there is a chance that the entire mass may detonate. Du Pont Red Cross Extra 20 per cent. dynamite can be used for this work at a great saving of time and labour during this busy season when every man and minute counts in tons of fertiliser mixed.

One or two men equipped with a du Pont No. 2 blasting machine, 250 feet of duplex lead wire, electric blasting caps, cap crimper, dynamite, and a shovel-handle for a tamping stick, can keep enough material shot down to ensure a ready supply for the mixing machines throughout the day. The main shooting should be done at the noon hour, and after the plant is closed for the day. This will encourage more careful loading and shooting, due to the absence of dust and other confusion, and it will also eliminate the loss of time resulting from idleness on the part of labourers while shooting is going on during working hours.

Charging and Firing Details.

Holes not smaller than one and one-half inch in diameter should be bored straight into the face of the bank about three feet from the floor. The depth of the holes can be from four to eight feet, or deeper, depending on the burden to be pulled down. Five to eight feet will be found about the correct depth under average conditions. The distance between the holes should be approximately the same as the depth; that is, if the holes are six feet deep, they should be six feet apart in a straight line across the face of the bank. The result to be obtained is to so place the holes and dynamite charges that the explosion will shoot out the bottom of the bank and cause the top to fall from its own weight. In some cases an overhang will be left at the top of the bank. This can be brought down usually with a single small charge loaded in a vertical hole from the top.

How much dynamite to use in each hole will depend on the material to be shot. Acid phosphate, for instance, is more gummy than the potash and nitrate salts, and breaks up less readily over a given radius from the charge. A safe rule to follow in loading the phosphate is to use one stick of 20 per cent. Red Cross dynamite, size 1¼in. by 8in., for every two feet depth of hole. Cartridges should be firmly pressed into the back of the bore hole with a wood tamping rod, the electric blasting cap being put in the last cartridge. Then the holes should be thoroughly filled and tamped, using acid phosphate or moist sand. This operation may be greatly facilitated by using du Pont tamping bags filled with sand or phosphate, or tamping bags may be made by forming stiff paper around a shovel handle or similar object.

After all holes are loaded and tamped, the electric cap wires should be connected in series to the lead wire and fired from the blasting machine. It will be found advantageous to use eight-foot electric caps to eliminate the necessity of splicing the connections and a possible cause of misfires. Lead wire can be made to give longer service if it is connected at the end of the line of holes instead of at the centre. Otherwise, it is frequently buried under a mass of

material and often has to be broken before it can be removed for the next shot. A charge of dynamite loaded in the above manner will bring down tons of phosphate, or other material, without danger to building or adjacent machinery.

However sceptical the manager may be at first about using dynamite in the plant, the necessity of keeping raw material supplies moving freely into the mill usually leads him to give explosives a trial as an emergency measure; and thereafter dynamite gets the job whenever the need for it arises.

CHEMICAL STONEWARE.*

MANUFACTURE, TYPES AND GENERAL USES.

CHEMICAL stoneware is a ceramic material made from specially selected clays and fired to the vitrification point. Properly manufactured it does not rely on a glaze, enamel, or veneer for its resistance to corrosive acids and chemicals, but the entire body throughout should be resistant. On such ware a plain salt glaze is put on for appearance, but plays no part in the wearing qualities. The salt glaze is applied by throwing salt on the kiln fires at their highest heat. This breaks up the salt, and the sodium combines with the clay on the surface of the ware to form sodium aluminium silicate, giving a smooth appearance and a neat look to the ware.

The clays as used for chemical stoneware (more than one clay is used and the clays are blended before using) are nearly pure aluminium silicate with but small traces of lime, magnesia, or iron. They should, usually, be also of the plastic type so they can be readily moulded.

Blending the Clays, Moulding and Drying.

The clays as received in the raw state are ground, washed, sieved, filter-pressed, and then blended and mixed and ground in a special machine again. The blends are then put into aging pits of concrete where they age for various periods. After aging the clays are ready for the workmen. Chemical-stoneware manufacture differs from ordinary stoneware, porcelain, or sewer-pipe manufacture in that in chemical stoneware but very little machinery is used. The work is almost entirely hand work by skilled men who must know how to read and interpret a blueprint. Machines for making chemical stoneware have been tried, but so far have not been found as satisfactory as hand production.

Orders for chemical stoneware are often accompanied by blueprints or special specifications. The job is assigned to a specific workman, who proceeds, from the clay already prepared and of the proper body, to mould the piece of ware in accordance with the specifications. The time required for moulding may be hours, days, or weeks, depending on the size and the design. When the piece has been moulded in accordance with the specified design, it is ready for the drying. Drying is accomplished in three ways—by natural air drying, in large heated rooms, and in automatic tunnel driers. Each has its specific use in accordance with the design, size, and thickness of the piece. Drying is one of the critical periods in the passage of the piece through the plant. The ware must be dried from the inside out, not from the outside in, or stresses will be set up in the structure which will later develop trouble in the firing. Also, the drying must not be too fast, for the same reasons. The clay shrinks about 5 per cent. in volume during drying, so this shrinkage has to be taken into account when moulding the piece.

Details of the Firing Process.

When the piece has been thoroughly dried both inside and out, it is ready for the kilns or firing. Firing in chemical stoneware requires two weeks, including the cooling of the kiln. The kilns used are circular with hemispherical roofs about 30ft. in diameter, and are known as periodic down-draft kilns—the fire passing downwards through the ware, through a false floor into the stack flues. The ware is piled in the kiln with the object of getting as much into the kiln as possible, consistent with getting it out again in perfect condition, and this setting of a kiln requires considerable experience on the part of the foreman kiln-setter. After the ware has been set, the openings are bricked up, and a moderate fire started in the fireplaces surrounding the kiln. The moderate fire is to drive off any remaining moisture mechanically held in the ware and to warm up the kiln slowly. The fires are gradually increased, and during this period—"the water-smoking period," as it is termed—the mechanically held moisture is driven off.

After tests made on the smoke passing through the flues to determine if further moisture is present, and none being indicated, the temperature is rapidly raised to about 1,000° F., at which temperature the water of crystallisation of the clay is driven off, the temperature being held at this and a slightly higher point for a predetermined time. (The recording pyrometers used indicate the general time.) This converts the clay into stoneware, but as far as chemical stoneware is concerned the firing is but half-completed. After the temperature for driving off the water of crystallisation has been maintained for the proper period, as mentioned above, the fires are pushed to their limit and the temperature gradually raised until it reaches the neighbourhood of 2,500° F., when complete vitrification or fusion of the body of the ware takes place. After this point is reached and held for a certain period, the fires are permitted to die down slowly, and when sufficiently low the fireplaces are bricked up and the entire kiln allowed to cool slowly by natural radiation. Thus, the ware is cooled slowly or, in other words, annealed, producing tough, strong structures which will withstand considerable rough treatment.

When the kiln is cooled off, the ware is removed from the kiln, taken to the warehouse, inspected, tested, checked, and packed for shipment.

Advantages and Limitations of Chemical Stoneware.

Of all the materials offered for use in industries where corrosive chemicals are manufactured or handled, chemical stoneware is probably the most versatile one in that it is practically immune from the attacks of every chemical except hydrofluoric acid, which acts on the silica in the clay. Of course, chemical stoneware also has its limitations and is not the Utopia in acid-resisting material, but for general all-round use there has still to be found a better material. The limitations of chemical stoneware are briefly—the limits as to size in which it can be made, tensile strength as compared to the ordinary metals, and that heating by direct flame cannot safely be done. To overcome the first limitation has been the aim of the manufacturers of chemical stoneware ever since they have been in business, with the result that every year larger and more complex pieces are produced, some reaching a capacity of 1,000gal. and over. To overcome the second, constant experiments are being conducted to improve the strength of the body, with the result that we have to-day ware that will withstand in some cases more punishment from mechanical injury than some of the compounded ferrous alloys. For the last, heating is substituted in the form of water, oil, and sand baths, or by steam injected into the solution by means of chemical-stoneware perforated pipes.

A Synopsis of Uses of Proved Value.

As to the designs in which chemical stoneware is made, it can be said that at this stage of its development almost anything mechanically possible can be and is made. In addition to the commoner forms or designs, the greater part of the manufacture of chemical stoneware is from blueprints or specifications furnished by the customer in order that the apparatus may be especially adapted for the specific process for which it is intended. As an illustration of the variety of products of chemical stoneware a few of the products in most general used are mentioned: towers and accessories therefor; tower packing; tile, brick, and blocks for construction of tanks, towers, vats, etc.; elevating apparatus for acids and corrosive liquids; receivers in the manufacture of acids; kettles, with or without stirrers; gas generators; jars; decanting jars; subliming pans; tanks; laboratory sinks; filters; coils; pipe and fittings in many styles and bores, return bends; S-pipe, vapour pipe; sleeve pipe, troughs, pipe dampers; faucets, cocks and valves; carboy stoppers; pitchers, jugs and buckets; dipping baskets, funnels, burner guards; etc. In other words, the field of requirements of the chemical and allied industries is practically covered. Specific mention may be made that chemical stoneware is used in plants manufacturing acids, alkalies, explosives, dyestuffs, pharmaceuticals, fertilisers, vinegar, foodstuffs, and mineral products, and for plating, lithographing, developing, and pickling processes.

Seven Types of Bodies.

It has been stated above that various types of bodies are produced to meet the needs of the different classes of equip-

* Paper contributed by M. A. Knight, of East Akron, Ohio, to the Symposium on Chemical Engineering Materials, held by the American Chemical Society in April. From *Industrial and Engineering Chemistry*, May, 1923.

ment. It is not to be understood that there are an indefinite number of bodies in general use, but rather that a reasonable number are employed. To be specific, the bodies employed by one manufacturer may be referred to as Nos. 1, 2, 3, 4, 5, 6, and 7.

No. 1 is a porous, open body, through which liquors will readily run, but which will hold hot acid gases. Finished unglazed, it serves for such uses as carboy stoppers, filtering plates and cups, electrolytic diaphragms, or any pieces subject to high temperatures and sudden changes.

No. 2 is a semi-porous, open, rough body, through which liquors will seep, but which is excellent for hot gases and for sudden changes in temperature. It finds use in baffle plates, heavy tile, covers and blocks for furnaces, and large pipe for hot gases. It is finished either glazed or unglazed.

No. 3 is a fine, close-grain structure, through which liquors are apt to sweat, but which is good for hot liquors and gases and uneven heat action. It is used for standpipe or fittings next to furnaces, muriatic acid sleeve pipe, boiling kettles, hot towers, burner guards, ejectors, and steam jets, and is finished smooth, bright, and glazed.

No. 4 has a tough, rugged, vitrified structure, not as close and fine a body as No. 3 or No. 5, but more vitrified and denser than No. 2. It will hold acid without seepage, and is used for large pieces of 250gal. capacity and over, for large tower pipe, kettles, and blow-cases, grillage tile, brick, heavy tanks. It is good for ordinary heat changes in temperature and is finished glazed and somewhat rough.

No. 5 has a close, dense, fine structure. This can be considered the general average body. It will withstand ordinary temperature changes, but not sudden changes. It is finished smooth with a bright glaze and is used for receivers, tanks, jars, drainage pipe, evaporating pans, condensing pipe, and sinks.

No. 6 is very fine, close, vitrified structure—closer and denser than No. 5. It will not stand heat action as well as the bodies previously described. It is used for acid pitchers, laboratory sinks, vacuum filters, funnels, flanged pipe, coils, tanks, jars, and other pieces where heat changes are small and slow. It is good for storage vessels, etching machines, chlorine pipe and fittings, etc. It is finished bright, clean, and smooth, with a heavy glaze.

No. 7 has a very fine, tight, close body, vitrified to almost a glass texture. It will not withstand changes in temperature or high temperature, but with this body there is no absorption whatever. It is used for valves, faucets, cocks, pebble-mill jars, distilled-water jars, small bore pipe and fittings, or any small pieces up to 50gal. capacity where there is very little heat action. It is finished very bright, smooth, with a glazed surface, and made up into only thin, light-weight, or small pieces.

General Characteristics.

A few words about the general characteristics of chemical stoneware are relevant. At first it was deemed necessary to make walls of apparatus heavy and thick, for mechanical strength as well as for resistant purposes. The present tendency is to make the walls as thin as possible, and it is surprising to note how thin they are made and yet combine strength and immunity to corrosion. In addition to the fact that the thinner walls make the apparatus lighter, they carry also the property of being better able to withstand the action of heat and cold and permit better radiation of heat in the case where heating is to be done or solutions are to be cooled off. It is the practice with chemical stoneware, where there is alternate heating and cooling, to avoid designs having sharp edges or corners, and to substitute rounded designs, since, inasmuch as chemical-stoneware bodies are of a crystalline nature and therefore require time for the molecules to adjust themselves to changes in temperature, the square design or sharp corners do not permit of even expansion or contraction and hence increase the liability to cracking. In this respect it should be mentioned that it is not the *degree* of heat or of cold to which the ware is subjected that has to be guarded against, but the *suddenness* with which the change from hot to cold or cold to hot is made, as well as the evenness with which heat or cold is applied.

Where chemical stoneware apparatus to an *exact* measurement is required, this is obtained by having the piece run slightly over in measurement and then grinding back to measurement. However, this is a long, tedious, and expensive operation, requiring the use of carborundum and machinery, and if exact measurements are not an absolute essential it is better to avoid this expense. Chemical-stoneware bodies are so hard and tough that nothing softer than carborundum will cut them with economy, and then only at a comparatively slow rate of speed.

Time Required for Manufacture.

The time required to manufacture chemical-stoneware apparatus varies with the size, design, and thickness of the piece, and runs from four to ten weeks. The greater part of the time is consumed in the drying and the firing of the piece, and in those two stages the time cannot be shortened with safety, no matter how necessary it may be to get the piece out faster. Hurrying the manufacture during drying or firing usually means the entire loss of the piece, with the result that the work must be started all over again from the beginning, with consequent still longer delay. It is therefore best to allow as much time as possible for manufacture when preparing plans for new installations or the repair or replacement of old.

CHEMICAL TRADE OF THE NETHERLANDS.

JUNE IMPORTS AND EXPORTS.

THE following statistics, which have been furnished by the Bureau voor Buitenlandsche Bedrijfsberichten, of The Hague, outline the import and export trade in chemical products of Holland during the month of June, 1923.

Imports of Chemical Products.

		Kilogrammes.	Florins.
Calcium acetate	Total	303,000	63,000
	Belgium	80,000	15,000
	U.S.A.	166,000	36,000

THE WORLD'S TRADE IN DIVI-DIVI.*

A TANNIN MATERIAL OF GROWING IMPORTANCE.

DIVI-DIVI is the native and commercial name for the dried seed pods of *Caesalpinia coriaria*, a small tree indigenous to tropical America. This tree grows to a height of 20 to 30ft., lives approximately 100 years, and bears fruit from its seventh year, though not reaching full development until its twentieth year. A mature tree will, under favourable conditions, yield as high as 300lb. of pods a season. The pods are 2 to 3 inches long, three-fourths inch broad, one-eighth inch thick, and very smooth. While drying they become curiously curved, frequently assuming an S shape. The tannin in these pods is exceedingly astringent, containing a large proportion of ellagitannin and gallo-tannin, also a considerable amount of oily and mucilaginous matter. The tannin content ranges from 40 to 45 per cent. This tannin occurs mainly in the tissues of the pod close to the outer skin, rather than in the seeds, which contain but little. A representative analysis of the pods is: Water, 13.5 per cent.; tannin, 41.5 per cent.; non-tannins, 18 per cent.; ash, 1.6 per cent.; and insoluble matter, 25.4 per cent.

Care Required in Handling Pods and Extract.

Great care must be taken in the handling of pods for export, for, as the tannin content of the pod occurs immediately under the epidermis, in the form of a white powder, any abrasion of the skin will result in loss of tannin. It is also essential that the pods be packed in fine bags rather than in those of coarse-grained material which would permit the powder to sift through and become lost in transit. Divi-divi readily adapts itself to separation into the concentrated extract form. Owing to the presence of a large proportion of carbohydrates and the foreign substance previously referred to, both the extract and the ordinary solutions for tannin purposes are subject to fermentation. Throughout the process of fermentation a deep colouring matter is developed which imparts to leather unsightly dark stains. The problem of effectively avoiding this fermentation has yet to be solved, although the risk can be materially lessened by use of antiseptics.

Increased Utilisation of Divi-divi in United States.

The use of divi-divi in the manufacture of leather was known to the Spaniards as far back as 1769, having been first imported into Spain from Caracas in that year. It advanced steadily in European favour during the succeeding 100 years, at the close of which period its use as a tanning agent had become widely extended. It was not, however, until 1915, when tanners found it necessary to utilise all available sources of tannin to meet the war demand for leather, that the use of divi-divi in the United States could be regarded as worth while. In that year the imports of divi-divi into America were fourteen times as great as the pre-war level, advancing to fifty-two times that amount in 1916, and attaining the peak in 1919, when statistics showed that imports increased to ninety times the 1913 receipts. The marked diminution in the 1921 imports reflected the general industrial and commercial depression of that year, while the improvement in the 1922 imports over those of 1921 bespoke a revival in the tanning industry. The American consumption of divi-divi in 1919 (the latest year for which statistics are available) amounted to 4,985 tons of pods, valued at 381,689 dollars, and 12,772,793lb. of extract, valued at 511,794 dollars.

Venezuela Most Important Source of Divi-divi.

Venezuela has long been regarded as the world's most important source of divi-divi. During the period 1908-1921 Venezuela's exports of divi-divi averaged 6,610 metric tons annually. This average includes yearly exports as high as 10,902 tons in 1911, and as low as 3,956 tons in 1920, and 2,849 tons in 1921; omitting the two low years, the average of the preceding twelve years was 7,145 metric tons. Should a greater demand for this product be created among tanners, Venezuela could increase its output several fold through harvesting of full crop and systematic cultivation. At present only that part of the crop most readily available is collected in sufficient quantities to fill market requirements.

Before the war, Germany was Venezuela's best market for divi-divi, which is utilised both as a tanning agent and dyestuff. Since 1915, however, the United States has become the principal purchaser. The January-April, 1923, imports of divi-divi into the United States aggregated 3,800,982lb., of which Venezuela furnished 2,116,392lb., or 56 per cent. The high cost of transportation during the war and the desire to eliminate all possibility of waste led to the establishment of two extract factories in Venezuela, situated at the ports of Porlamar and La Guaira. At each of these plants the pure tannin is extracted from the pods—by means of a patented process into which neither heat nor the use of any chemical composition enters—and put up in pressed tablets. It is claimed that the tablets, or cakes, ready for export contain an average of 80 per cent. tannic acid and 16 per cent. tannic glucose. No export figures of divi-divi extract are available.

Divi-divi Trade of Colombia.

Colombia ranks second to Venezuela as a source of divi-divi. The estimated total annual output is 7,500 tons, the bulk of which is produced in the Goajira Peninsula and exported through the port of Rio Hacha to Curacao for transshipment. Decreased demands during the post-war industrial depression produced a general dullness in Colombian trade in divi-divi rather than lessened supplies; but, judging by recent United States imports from Curacao (the greater proportion of which came originally from Rio Hacha), Colombia must be renewing its former activity in this product.

Divi-divi Exports from West Indies.

The Dominican Republic's exports of divi-divi formerly exceeded 2,000,000lb. annually, almost all of which was produced on the arid lands of the Province of Monte Cristi. The output, however, has been seriously affected in recent years by the presence of a species of orchid, which lives as a parasite on the divi-divi tree, frequently killing it, and in every case reducing the yield of pods. Until measures are introduced to eliminate this pest no great increase in exports may be anticipated. The present annual production of the Dominican Republic and Haiti is estimated at 1,500 tons. Of the United States imports of divi-divi during the first four months of 1923 the Dominican Republic provided none in January, 54,810lb. in February, 56,000lb. in March, and 518,362lb. in April.

As a general rule divi-divi pods are leached by the tanner. If passed through a disintegrator the pods are readily broken and the rich tannin powder sifted out, which is mostly soluble in water. A liquid extract containing 25 per cent. tannin is an article of commerce. Divi-divi is rarely used alone, because the leather thus produced is strongly affected by atmospheric conditions, being soft and spongy in damp weather and lacking pliability in periods of drought. To counteract these tendencies divi-divi is usually mixed with other tanning materials. If used in strong liquors it yields a heavy and firm leather. Ordinarily it is employed as a substitute for gambier in the dressing of leather, and in the rapid drum tannage of light leathers, through means of which an excellent colour may be obtained. Occasionally its use in connection with leather is merely as a dye.

Freight Rates and Prices from South American Ports.

Freight has always constituted the dominating factor in the delivered price of divi-divi, for, owing to its bulkiness, its stowage, packed in sacks, requires 110 cubic feet to the ton, which, in times of tonnage scarcity, has rendered transportation extremely difficult. Prior to the war ocean freight on divi-divi (which was usually handled by small sailing vessels) was 8 dollars per ton; in 1919, however, it was 24 dollars per ton from Colombia to New York. Present ocean freights from Venezuela to New York are 7.50 dollars to 8 dollars a metric ton.

Previous to 1914 Germany practically controlled the tanning-material market of South America and Hamburg fixed the prices. The price assigned to divi-divi was from 1½ to 2 cents a pound according to grade and origin. In 1883 the price of divi-divi at Venezuelan ports of shipment was 23.16 dollars per metric ton of 2,204.6lb.; in 1919 it ranged from 13.51 to 19.30 dollars at Cumana, and from 21.23 to 27.02 dollars at Maracaibo. During the war prices attained a peak of 75 dollars per ton, but in the early part of 1918 divi-divi was marketed in New York at 50 to 55 dollars per ton. The general trend, however, in 1922 and the January-June period of 1923 has been toward the pre-war level, prices having fluctuated between 38 and 39 dollars per ton during that period.

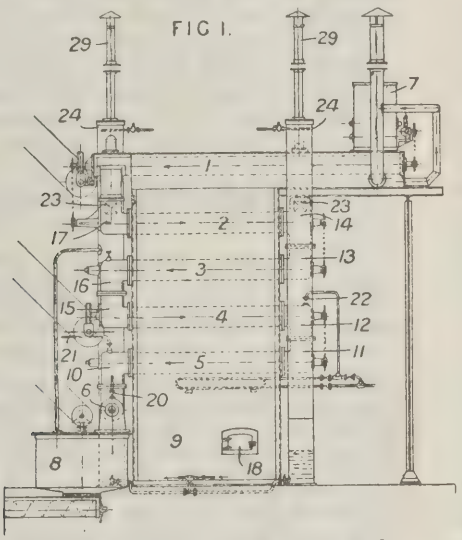
* From account by Mr. H. M. Hoar, of the U.S. Bureau of Commerce. Abstracted from *Commerce Reports*, July 2, 1923.

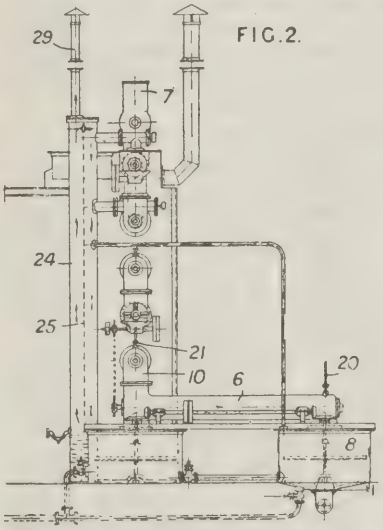
ACTIVATED CHARCOAL.

PROPOSED NEW DUTCH MANUFACTURING PROCESS AND CLASSIFICATION SYSTEM.

IN connection with the article on activated carbon which appeared in our issue of July 27 (page 99), and with the growing importance of this material as an agent for the purification of liquids and gases, the description of two patents which have been applied for, in the one case (*Brit. Pat.*, 198,328) by the Algemeene Norit Maatschappij (known as the General Norit Company, Ltd.) and the other by J. N. A. Sauer of Amsterdam (*Brit. Pat.*, 198,373) should be of interest to our readers.

The first patent deals with the manufacture of active charcoal, and is a process for producing uniformly active charcoal or for regenerating spent charcoal of the type in which a carbonaceous material is distilled in the presence of active gases and is characterised in that the raw material, which may be the less porous kinds of coal and carbonaceous materials such as brown coal, anthracite, etc., is first granulated or pulverised preferably uniformly and then agitated during the heating and action of the activating gases, the agitation being affected for example by stirring, by rotation of the retort, or by the kinetic action of gases. The raw material may be subjected to a preliminary dry distillation in which the products of distillation are quickly swept away, such as by the passage of practically inert gases. The activating gases specified are steam, carbon dioxide, carbon monoxide, air, oxygen, chlorine, hydrogen, flue gases and generator gases, and an apparatus for carrying out the process in a continuous manner consists of a hopper 7 with automatic feed mechanism, which charges the material to a trough 1 with a worm conveyer, whence it passes successively to retorts 2-6 of chamotte or a refractory alloy, all of which have worm conveyers.





Retorts 2-5 are disposed within the brick walls 9 of a furnace 18 the unions 10-17 being exposed. Gases may be blown into the retort 6 at 20, into 5 at 21, and into 4 at 22, the retort gases passing by outlets 23 to wide pipes 24, divided by partitions 25, and having water-chambers at their bases to collect suspended carbon, and chimneys 29. An example shows the production of active charcoal using already carbonised material, air preferably diluted with nitrogen being admitted to retort 6, flue or generator gases to retort 5 and steam to retort 4, the injection beginning as soon as material makes its appearance at the water-sealed or enclosed chamber 8 into which the finished product is delivered.

The Six Types of Activated Carbon.

The second patent deals with the methods of purifying liquids and gases with activated charcoal, and states that the liquid or gas to be purified is subjected to the action of a plurality of active carbons possessing different physical and physico-chemical properties, and so chosen that they supplement one another in their action. The different types of carbon may be employed in admixture with one another or consecutively. Six types of activated carbon are distinguished.

Type 1 comprises carbons produced from materials of vegetable origin and activated by means of gases such as superheated steam or carbon dioxide at a temperature of 800-1,200° C. Included in this category are the carbons sold under the names "Norit," "Eponit," "Batchite" (from coal), and "Dorsite" (from cocoanut shells).

Type 2 comprises carbons produced by dry distillation at temperatures of 200-2,000° C. of organic raw material such as peat, sawdust, seaweed, or pine needles admixed with, or naturally containing, inorganic materials such as alkalies or alkaline earths, lime salts, or sulphuric acid. The product is generally extracted, for example, with acids, leaving a carbon which is stated to have no pronounced structure and to be a poor filtering medium. Such carbons are those under the names "Carbrox" (from rice or cotton), "Kelpchar" (from seaweed), "Darco" (from lignite), and "Delclowyte" (from peat). Type 3 comprises carbons produced by calcination and subsequent extraction of a solution of cellulose, molasses, or other carbon-containing materials in a suitable solvent such as concentrated zinc-chloride solution, hydrofluoric acid, or sulphuric acid. A modification of the process consists in coking the raw material and extracting the residue with a substance such as selenium oxychloride which dissolves the coking products. Carbons of this type are stated to be very finely divided and unsuitable for filtration, but to be active absorbing agents. The carbons sold under the names "Carboraffin" (zinc-chloride carbon), "Filtchar," "Super-filtchar," "Sugar" or "Suchar," and "Sulphite-carbon," the last four of which are prepared from sulphite-cellulose liquors, are included in this category.

Type 4 comprises carbons produced by adding kieselguhr or other porous inorganic materials to the solution to be treated by the process giving carbons of type 3, or to starch and other carbohydrates which are then subjected to dry distillation. Such carbons are stated to be poor filtering and decolourising agents. The carbon sold under the name "Molaschar" is referred to in this connection. Type 5 comprises carbons produced by dry distillation at temperatures of 400-600° C. of materials, generally of animal origin, which naturally possess the property of yielding decolourising carbons, such as bones, blood, fish, and the residues from the removal of fusel oil from alcohol. Such carbons, after extraction, as with acids, are stated to be active absorbing agents but poor filtering media. They include ordinary bone charcoal, "Noir Epuré" (extracted bone charcoal), "Noir lavé en Pâte" (bone charcoal extracted with sulphuric or hydrochloric acid and sold as a paste containing 80 per cent. of water), blood charcoal, and the varieties sold under the names "Bactanat" (from fish), "Flandac," "Flaming," and "Littoral." Type 6 comprises decolourising carbon prepared from gases. They are in general poor filtering and decolourising agents.

Use of Mixtures of Activated Carbons.

The invention is illustrated by reference to the purification of sugar solutions, glycerine, oils, and fats, the treatment of wine, and the separation of one or more constituents of a gaseous mixture. The carbons employed may be treated with substances that are capable of enhancing their effect or of preventing undesired subsidiary reactions. For example,

sodium phosphate is added to active carbon for removing iron from glucose solutions. Oils and fats containing fatty acids may be treated with a mixture of active carbons, one of which has been impregnated with lime. Gelatin may be added to the carbon used in the treatment of wine, and acid to that used in the clarification of sugar solutions. The application of the invention to the treatment of gaseous mixtures is described by reference to the removal of hydrogen sulphide and benzol from illuminating gas by the use of a mixture of two kinds of active carbon. The benzol can afterwards be recovered by treatment with superheated steam or by heat, and sulphur resulting from the oxidation of hydrogen sulphide by the oxygen in the charcoal may be recovered by means of superheated steam or removed by oxidation.

THE RRITISH CHEMICAL PLANT MANUFACTURERS' ASSOCIATION.

THIRD ANNUAL GENERAL MEETING.

AT this meeting which was held at 106, Piccadilly, London, W. 1, on Wednesday, July 18, there were present: Mr. L. M. G. Fraser (in the chair) (W. J. Fraser and Co., Ltd.), Mr. E. A. Alliott (Manlove, Alliott and Co., Ltd.), Mr. F. R. Blizzard (T. and C. Clark and Co., Ltd.), Mr. H. Broadbent (Thomas Broadbent and Sons, Ltd.), Mr. J. H. Rawson (The Widnes Foundry Co., Ltd.), Mr. W. A. Sheppard (Joseph Baker, Sons, and Perkins, Ltd.), Mr. E. Cecil Watkins (W. Neill and Son, Ltd.), Mr. J. W. Wright (The Cannon Iron Foundries, Ltd.), together with Mr. W. J. U. Woolcock, Mr. A. J. Malacrida, and Mr. G. J. Alderton. An apology for absence was received from Mr. James Robinson (Mather and Platt, Ltd.).

Representation on Scientific and Other Committees.

The Chairman, in moving the adoption of the annual report, said: The number of our members is, I believe, one less than last year. The balance-sheet shows that your financial position is an increasingly sound one. We started with a balance of £177. 7s. 8d. and carry forward to next year a balance of £264. 13s. 8d. This Association does not have meetings at which theoretical papers are read and discussed, but being composed of manufacturing engineers, its purpose is the improvement of the relationship of its members to the chemical manufacturers either by propaganda, or discussion of any technical or business problems that are brought forward by its members, and its prosperity is to be judged rather by the effective aid it can give than by the number of meetings held.

An Association pre-supposes two things—energy and direction of energy. The first must be supplied by the members in general, and the second is the work of your Committee and its officers, who are ever-ready to meet and to direct the discussion on any problem sent in by members, into the best channels for solution. If we are able to apply the results arrived at by scientific men, if the laboratory experiment of to-day is to be our engineering achievement of to-morrow, we ought to be very much alive to all that is going on in the scientific world. Let us, therefore keep our vision firmly fixed on present needs, but tune our minds to the edge of the beyond.

I should like to see members of this Association invited on to the councils of theoretical and research societies and associations where their engineering knowledge would probably help in the solution of many difficulties from the mechanical science or engineering points of view, and probably rescue from failure many problems that appear almost insoluble.

Disappointing Results with Standardised Plant.

The results of the suggestion made at the last annual meeting have not been quite so effective as was hoped. This Association was incepted at the call of the chemist, and a great deal of work has been carried out by your Committee in standardising various types of plant such as jacketted pans and filter presses. The manufacturers have altered their patterns and incurred great expense for the ultimate advantage of the chemical manufacturers, and they had hoped that their advances would be better appreciated. Further this information has been published and made available to other manufacturers who have incurred neither the expense nor trouble of the work entailed. We have, therefore, again brought this subject to the notice of the Association of British Chemical Manufacturers. One suggestion I would like to make is that where a member cannot himself undertake any particular piece of work he should give other members of the Association the opportunity of doing so.

I regret to find it has not been possible to obtain sufficient support to have a section at the British Empire Exhibition of 1924, especially as the Chemical Section is going to have such a large display, and many chemists must be drawn to this exhibit, within whose precints we should have been housed.

Work of the Joint Research Committee.

The study of corrosion is one of absorbing interest, and it is not yet possible to formulate with certainty any definite principles on the subject. The absence of such definite knowledge is a source of difficulty to us as plant manufacturers. I think, however, that our iron founders can do a great deal for us in more technical research as to their mixtures, sands used, temperatures and rates of cooling, with the object of giving us a closer grained and stronger metal. In view of the fact that cast iron is composed of crystals and a matrix, it would perhaps be worth while making research in this field when we consider how small a defect will form a starting point for corrosion. The matrix being the softer becomes attacked and the formation of chemical salts starts corrosion by electrolytic action. It would perhaps be helpful if our Association were represented on the Cast Iron Research Association.

The Joint Research Committee has done a considerable amount of work under the Chairmanship of Dr. Seligman. Chromium steel was very thoroughly investigated and your Sub-Committee had many interesting and useful discussions with Dr. Hatfield, who gave a great deal of his time to us, and a very great amount of experimental work has been carried out under his care. The manipulation of this metal is difficult owing to its hardening above the critical temperature, and it has then to be annealed before further work can be carried out, with a subsequent tendency to scaling. This material is only non-resistant to certain chemicals and the scaling makes it less so, but work is being carried out in this direction which, I hope, will lead to satisfactory results.

After numerous tests of small pieces of nickel and small crucibles it was found that the results of chemical action were not consistent, and varied considerably with the composition of the nickel and the after working thereof.

The Education Problem.

This ever-present and much debated subject was brought up before your Committee, and an interim report was presented to the A.B.C.M. in which the characteristics and training of a chemical engineer were discussed. The subject is full of difficulties not only with regard to the drawing up of the curriculum to be followed, but also in persuading the authorities to change their methods so as to correspond with our ideas. I am afraid, if care is not taken, that the real point will be missed under the haze that has been raised round the term "chemical engineer," and I think this Association might well formulate their own suggestions for use at the proper time. I hope, therefore, that we shall have a member on any representative Committee that seriously takes up the question. The tendency of the present day is too intensive education, and a much broader education would be of far greater use to the great majority of men.

You have had sent to you the report of the Sub-Committee on Standardisation of Cast Iron Filter Presses. The specification there set out has been adopted by the British Engineering Standards Association, and calls for little comment from me. I would tender our thanks to the Sub-Committee, under the chairmanship of your treasurer, Mr. Alliott, for the care and thoroughness with which they have carried out this work. It has, I know, involved numerous meetings and discussions and a great deal of drawing out of plans and details. I cannot do better, and I am sure I have you with me, than endorse the letter sent to Mr. Woolcock by the Secretary of the British Engineering Standards Association in which he concludes: "The acceptance of the proposals submitted by your Joint Committee without any important alterations is a further tribute to the care and thoroughness with which the work has been carried out by that Committee."

Improvement in Railway Traffic Conditions.

Reductions in Rates.—In August last the rates were reduced from 100 per cent. to an average of about 75 per cent. plus flat rates, above the pre-war, and in May of this

year the percentage was reduced to about 60 per cent. plus the flat rate. Application is at present before the tribunal for a reduction to 33 per cent. above pre-war.

Conditions of Carriage.—In regard to the terms and conditions under which general merchandise will be carried, the conditions for "company's risk" traffic have now been settled and the most important feature about the conditions is that for the first time in the history of railways the contract will include a definite statement of the carrier's liabilities. Even in those cases where the railways are generally exempt from liability such as from the Act of God, the King's Enemies, etc., companies have still to show that they used all reasonable care and foresight in dealing with the merchandise.

Forms of Schedule.—Forms of Schedules for the new rates have been fixed by the Rates Tribunal, and the traders have been able to secure some concessions in the methods of basing rates which should prove of great advantage to the trading community generally.

Mr. Blizzard, seconded, and the accounts and report were unanimously adopted.

Election of Officers and Committee.

Mr. L. M. G. Fraser (W. J. Fraser and Co., Ltd.), Mr. F. R. Blizzard (T. and C. Clark and Co., Ltd.), and Mr. E. A. Alliott (Manlove, Alliott and Co., Ltd.), were unanimously re-elected as chairman, vice-chairman and honorary treasurer respectively for the coming year.

The following gentlemen were elected members of the Executive Committee for the ensuing year:—Mr. H. Bush (Huntington, Heberlein and Co., Ltd.), Mr. J. H. Rawson (The Widnes Foundry Co., Ltd.), Mr. James Robinson (Mather and Platt, Ltd.), Dr. R. Seligman (Aluminium Plant and Vessel Co., Ltd.), Mr. E. C. Watkins (W. Neill and Son, Ltd.), Mr. J. W. Wright (The Cannon Iron Foundries, Ltd.).

THE CHINESE CAMPHOR TRADE.*

DECLINE IN EXPORTS FROM HONGKONG.

CAMPHOR has for long been an important article of export from Hongkong. In South China camphor is produced in the three Provinces of Kwangsi, Fukien, and Kiangsi, while a small quantity also comes from the Kwangtung Province. That of Kwangtung and Kwangsi is inferior in quality to the camphor of Fukien and Kiangsi. The island of Formosa, where the Japanese Government holds a monopoly, supplies the largest portion of the world's camphor, but South and Central China are also important producers.

Owing to there being no system of replanting, the number of trees has been gradually decreasing until Fukien's supplies are nearing exhaustion. It is reported by natives, however, that there are many untouched camphor-wood areas in the Province of Kiangsi, while the more inaccessible regions of Kwangsi and Yunnan are also said to contain considerable numbers of trees.

According to the statistics issued by the superintendent of imports and exports of the colony of Hongkong, exports of camphor of the amounts shown in the following table and values left Hongkong during 1920, 1921, and 1922:

During the war and up to the time of the general world trade depression in 1920 the camphor trade was abnormally large, especially with the United States, England, and France. Since 1920 shipments to these countries have dropped off considerably, and during the year 1922 India held first place as a purchaser of camphor from Hongkong, with the United States ranking second. India has always been an important buyer of this product. Crude gum camphor is the principal kind exported from Hongkong, both the crude Fukien and Kwangsi varieties being shipped in large quantities. Refined camphor is only sold in insignificant quantities, as the native methods of refining are both primitive and expensive. Camphor oil is also only exported in small quantities, mostly to Calcutta.

Reasons for the Decline.

According to dealers there are several reasons for the decline in camphor exports from Hongkong during the past few years. The political condition in South China is one of the foremost causes, since military operations have constituted a serious hindrance to the free movement of supplies from the interior and have resulted in certain military leaders levying heavy imposts on transit goods. Another factor which has contributed to the decline of the trade in this commodity is the growing importance of Kiangsi as a producer. The industry has rapidly developed in that province, and a substantial portion of the demand which was formerly met by shipments from Hongkong is now being filled by the product of Kiangsi, exported *via* the port of Kiukiang.

* Abstract of a report by W. J. McCafferty, U.S. Consul at Hongkong, and published in *U.S. Commerce Reports*, July 23, 1923.

† 1 picul = 133⅓lb.

Methods of Sale, Packing, and Prices.

The bulk of the production of camphor from Fukien and Kwangsi Provinces is shipped to Hongkong and consigned to native traders. These native traders sell to export houses, who, in turn, sell to the consuming markets. Certain firms in Europe and America have arrangements with some particular Hongkong exporting house for the purchase of their supplies. Crude camphor is generally packed in zinc or tin lined cases having a capacity of 1 picul. The usual container used in shipping this commodity measures 4½ cubic feet. Camphor oil, on the other hand, is usually exported in cases containing two old kerosene tins, which hold about 65 pounds to the case.

Sellers guarantee the merchandise to analyse 90 per cent. camphor and the oil to be of a guaranteed specific gravity upon arrival. If the analytical test shows a lower percentage, it is customary for the sellers to allow the buyers a rebate on the price of the camphor. The usual rebate is three-eighths of 1 per cent., United States currency, per pound for each unit under 90 per cent. Contracts of sale to the United States are ordinarily governed by the clause "landed net weights," that is, the sellers undertake to indemnify the buyers for any difference between the invoice weight and the weight as ascertained upon arrival. It is also the custom for the purchasers to provide the exporters with a confirmed letter of credit at 90 days for the full invoice value.

The price of Fukien and Kiangsi camphor, which is considered of the best quality, at the present time is about 160 Hongkong dollars (1 Hongkong dollar = 0.4777 American dollars at normal and 0.5221 American dollars at current rate of exchange) per picul, while the inferior grades from Kwangtung and Kwangsi are sold at about 155 dollars per picul. The better grade of camphor oil is being sold at present for approximately 26 dollars per picul, and the inferior at about 18 dollars.

German Production of Dyestuffs.—According to information supplied by Dr. Breithut, the recently appointed U.S. Chemical Trade Commissioner to Europe, the output of German dyestuffs during May of this year amounted to 7,454,092lb., made up as follows:—Alizarin red, 253,264lb.; indigo paste, 47,740lb.; vat colours, except Indanthrene Blue G.C.D., 269,526lb.; Indanthrene Blue G.C.D., 1,434lb.; alizarin colours other than red, 172,753lb.; direct colours for cotton, 2,420,202lb.; direct colours for diazotisation, 158,418lb.; acid colours for wool, 1,405,122lb.; chrome colours for wool, 712,158lb.; basic colours, 30,916lb.; sulphur colours, 1,567,896lb.; lake colours, 144,663lb.

NOTES ON THE ITALIAN CHEMICAL INDUSTRY.

(From Our Own Correspondent.)

Synthetic Petroleum and Benzine.—Consequent upon the successful production of synthetic petroleum and benzine in Germany, Italian technicians are studying the possibility of introducing these processes into Italy, using for the purpose powdered lignite. (Italy consumes about four hundred thousand tons of benzine and petroleum per year, and this quantity has a tendency to increase still further owing to the great development of motoring and aviation. Most of the requisite benzine and petroleum has to be imported and represents for Italy an expenditure of one half milliard lire per annum.) The transformation is effected by treating powdered lignite with a stream of hydrogen under a pressure of one hundred atmospheres at about 200° C. The quantity of hydrogen necessary to obtain petroleum is five per cent., whereas that required for producing benzine is ten per cent.

Italo-Austrian Tariff Convention.—This tariff convention, in its clauses relating to chemicals imported from Austria into Italy, fixes an import duty of 8 gold lire per kilogramme for compressed carbonic acid, of 2.5 gold lire for sulphate of copper, of 25 gold lire with a coefficient of increase of 0.2 for hydrogen peroxide, of one gold lira for sulphate of ammonia. Austria exempts from import duty crude Italian sulphur in blocks or sticks, ground sulphur, flowers of sulphur, mercury, crude boric acid, crude borax, crude tartaric acid, citrate of lime, superphosphates, and calcium cyanamide; and places a duty of 8 gold lire per kilogramme on refined boric acid, 24 gold lire on pure tartaric acid, 24 gold lire on pure citric acid, 1 gold lire on sulphate of ammonia to be employed as fertiliser, 7 gold lire on refined borax, 3.60 gold lire on sulphate of copper and copper-containing insecticides and fungicides, a duty of 15 gold lire on common soap, etc.

General Tariff Notes.—By the new customs tariffs approved by the Chamber of Deputies the import duty on hydrochloric acid and sulphuric acid is removed; the duty on soda crystals, is increased from one to two gold lire and the duty on calcium chloride increased from one to one and a half gold lire. To compensate for the reduction in the State revenue, brought about by lower taxes on certain imported food products, the Government have decided to raise to 140 lire the present tax on the production of alcohol. Denatured alcohol to be used for power, heating, lighting, and other industrial purposes however is free from tax.

Reduction in Sicilian Sulphur Stocks.—By a recent decree, 125,000 tons of sulphur sold to the British National Sulphuric Acid Association, will be taken entirely from the remaining stocks of the Consorzio Obliggatorio per l'Industria Zolfifera Siciliana, at Palermo. The money obtained from this sale will be devoted wholly to the payment of the debts of the said Consortium, and will allow of a reduction in the number of the debentures. It is expected that all the debentures will be repaid by the Consortium within eight years.

Italian Production Statistics.—Italian production of mercury attained about 1,530 tons in 1922, against 1,071 tons in 1921, 1,410 tons in 1920, 548 tons in 1919, 985 tons in 1915, 1,070 tons in 1914, 1,000 tons in 1912, 955 tons in 1911, and 894 tons in 1910. The production of olive oil reached 277,600 hectolitres in 1922, against 161,500 hectolitres in 1921, 203,900 hectolitres in 1920, 289,000 hectolitres in 1918, 206,200 hectolitres in 1916, 178,400 hectolitres in 1914, 95,800 hectolitres in 1912, and 138,460 hectolitres in 1910. From July 1, 1922, to April 30, 1923, Italian production of alcohol reached 360,600 hectolitres, of methyl alcohol 415 hectolitres, of acetic acid 602 tons, of glucose 7,900 tons, of soap 110,913 tons, and of seed oils 31,792 tons.

Italian Overseas Chemical Trade.—During the last fortnight of July there were imported into Genoa 912 tons of pig iron and other metals, 290 tons of copra, 15,040 tons of phosphates, 600 tons of cellulose, 1,573 tons of quebracho extract, 980 tons of caustic soda, 690 tons of other chemicals, 50 tons of colours and varnishes, 3,004 tons of burning and lubricating oils, 2,500 tons of naphtha, 240 tons of tallow, 100 tons of paraffin, 50 tons of gum, 200 tons of china clay, etc. From July 1, 1922, to June 20, 1923, there were imported 104,421 tons of petroleum, and 109,863 tons of benzine, against 94,613 tons of the former and 94,020 tons of the latter from July 1, 1921, to June 20, 1922. During the first five months of this year Italy imported chemicals, medicinals, resins and colouring matters to the value of 490,686,700 lire, against 469,871,929 lire during the same months of 1922; and exported similar materials to the value of 157,545,537 lire, against 161,678,538 lire in 1922.

Improvement in Italian Financial Conditions.—Data collected by the Associazione Bancaria Italiana, regarding the activities of limited companies during June last, show a total increase of 524,455,400 lire distributed over 115 companies. During the same period 157 new companies with a total capital of 94,387,750 lire were founded. The total capital invested reached 618,843,150 lire. There were 54 failures of limited companies to the value of 56,001,800 lire, and 39 reductions of capital to the value of 61,148,925 lire.

Fertiliser News.—Italian consumption of Chilean nitrate in 1922 fell below anticipations, only reaching 25,000 tons. The use of nitrate of ammonia amounted to only 10,000 tons, against 12,500 tons in the preceding year. At the Terni works and the Piano d'Orte works of the Società Azotati plants for the production of sulphate of ammonia starting from calcium cyanamide were put into operation. The consumption of sulphate of ammonia during 1922 was low, not more than 15,000 tons, as against a pre-war average of 35,000 tons.

Company News.—At Rome a new firm, the Società Italiana per le Applicazioni dell'Ozono, with a capital of 100,000 lire was established, for the production and application of ozone. At Castellammare di Stabia, near Naples, there has been formed the Società Commerciale G. Monti e C., with a capital of 100,000 lire, for the production of and trade in chemicals. At Montevarchi the wood distillery of Distillazione Legna S.D.L. was founded with a capital of 300,000 lire. The Fabbrica Lombarda di Prodotti Chimici of Milan, made, during its past financial year, a net profit of 292,720 lire on a capital of 3,000,000 lire. The Consorzio Produttori Soda e Cloro of Milan, at an extraordinary meeting, decided to go into voluntary liquidation owing to bad trade. The profits made by the Società Anonima Ossinitrica of Genoa on a capital of 500,000 lire have allowed this firm to make good the losses experienced in the years 1920 and 1921, and still leave a net profit of 3,794 lire. The Società Generale per la Ciannamide of Turin, as a consequence of the results of the last financial year which show a total loss of 5,569,179 lire, has decided at an extraordinary meeting, to reduce the capital from 3,750,000 to 3,00,000 lire, by lowering the nominal value of the shares from 100 lire to 20 lire.

THE CHEMICAL INSTITUTE FOR IRELAND.

GENERAL PURPOSES COMMITTEE APPOINTED.

THE decision to form an Irish professional institute for chemistry on the lines of, and with the approval of, the British Institute of Chemistry was recorded in our issue of July 6, 1923. The matter has now been carried a stage further, for a committee has been formed to put into effect the general purposes of the Chemical Institute for Ireland—namely:

Objects of the Institute.

(1) That all chemical operations in Government laboratories, or institutions, or in other laboratories supported wholly or partially by public funds, be under the direct control of a registered professional chemist.

(2) That in Irish courts of law only registered professional chemists be permitted to give expert chemical evidence in penal cases.

(3) That public analysts be registered professional chemists, and that they shall conform with all requirements of the controlling board in connection with their duties as public analysts.

(4) The maintenance of a high standard of efficiency on the part of registered professional chemists.

The committee have drafted regulations for the training of chemists desirous of becoming members of the Institute. As recorded in our earlier account, the course of training extends over a minimum period of four years, and a register will be maintained of chemists qualified to take part in chemistry as applied to industrial, analytical, and agricultural work, as well as research and teaching. According to the *Chemist and Druggist*, it is the intention of the committee to apply at an early date for formal recognition, by charter or otherwise, of the proposed Chemical Council as the authority for the registration of professional chemists. The honorary secretaries are Joseph Algar, D.Sc., and A. G. G. Leonard, Ph.D.

SAFEGUARDING OF INDUSTRIES ACT.

METHOD OF PAYMENT OF DUTY UNDER PART I.

THE British Chemical and Dyestuffs Traders' Association has just forwarded to H.M. Treasury a Memorandum on the method of payment of duties under the Safeguarding of Industries Act, 1921, Part I. Copies have also been sent to H.M. Customs. The following is a copy of the Memorandum:—

Importers of goods scheduled under Part I. of the Safeguarding of Industries Act, 1921, have to pay the duty of 33⅓ per cent. at the time the goods are landed and cleared at H.M. Customs. This procedure, it is understood, is governed by Section 39 of the Customs Consolidation Act, 1876, whereby H.M. Treasury are given power to decide whether goods liable to import duties shall be allowed to be bonded or not. The Treasury Order in respect of the Safeguarding of Industries Act, 1921, stipulated that the duties should be paid at the time of landing and clearance of the goods at H.M. Customs. During the period this Act has been in force it has been found that the present method of payment of duties as outlined above is, in many ways, having a detrimental effect on the commerce of this country. The following points are submitted in support of this view:—

Difficulties Entailed by Present Method.

1. Prior to the introduction of the Safeguarding of Industries Act and the import duties it entails, merchant importers were in the habit of holding as stocks bulk supplies of goods, and were thus enabled to meet both home and overseas demands without delay. The re-exportation aspect was then of very considerable importance, it being estimated that quite half the volume of imports now liable to Key Industry duty were, when previously allowed free import, disposed of by way of re-export sales. Careful and exhaustive inquiry has been made as to what effect the payment of import duties under the Act has had on this important branch of the chemical trade, and it has been found that:—

(*a*) The difficulties and uncertainty of obtaining "drawbacks" of duties paid at the time of importation make it impracticable for merchants to compete in overseas markets. For instance, unless a merchant holding stocks of goods on which duty under this Act has been paid can ascertain definitely and quickly whether he can recover such duty upon re-exportation he is unable to arrive at his selling price, and is thus prevented from competing for overseas business. It is certain that if he does not allow for a "drawback," his price to the foreigner would not be competitive.

(*b*) That on account of this position the volume of re-exports of goods liable to Key Industry duty has fallen away in a very deplorable manner, and merchants are continually complaining that they have lost and are still losing such business, and state that it is largely due to the disadvantages arising out of the present method of collection of duties levied under the Safeguarding of Industries Act, 1921, Part I.

(*c*) Some firms, in an endeavour to overcome this barrier to re-export trade, are now holding stocks at Continental ports and meeting demands in that way. This must entail loss of freights to the shipping interests of this country; loss of employment at the docks, in warehouses, and in various other directions. It has been found that in this way only is it possible and practicable for merchants in this country to hope to compete successfully in overseas markets.

(*d*) Claims for drawbacks usually take a considerable time to settle, and in many instances where the goods in question have, since their importation, changed hands one or more times, it has been found almost impossible to satisfy H.M. Customs as to their identity. While the merchant is attempting to overcome these difficulties the overseas business is lost.

2. As regards sales of dutiable goods in this country, merchants, in order to carry on their business as economically as possible and to fulfil their function as distributors, are in the habit of importing in bulk quantities. Such goods are gradually liquidated and in many instances the duty paid at the time of importation may not be recovered in full for twelve months, or even longer. In this way considerable amounts of capital are locked up, to the detriment of the merchant and trade in general.

B.C.D.T.A. Request That Goods Should Be Bonded.

It is submitted that, in the case of re-exports, if merchants were given the opportunity of putting goods liable to Key Industry duty into bonded warehouses at the time of importation, and thus be relieved of the immediate payment of duty and the uncertainty of obtaining drawbacks, the trade of this country in re-exports of chemicals would be materially facilitated and would undoubtedly increase in volume. In the case of sales to buyers in this country, duty would only be paid at the time they were taken out of bond for actual delivery. Under this arrangement comparatively large amounts of capital would be at the importers' disposal, instead of being locked up as is the case under the present conditions.

Consideration has been given and inquiry made as to whether there would be objection on the part of warehouse interests to accepting goods scheduled under Part I. of the Safeguarding of Industries Act, on account of their dangerous character in themselves or when stored with other goods. It appears that as these materials are packed in such a manner as to satisfy shipping lines, who accept them at ordinary rates, and, for the same reason, insurance of such goods is effected at low rates, it is believed that warehouse interests would approve of the suggested system of bonding.

It is therefore suggested that, as the present system of collection of duties under the Safeguarding of Industries Act, 1921, Part I., is doing great harm to the commerce of this country, especially in the matter of re-exports, the Order made by H.M. Treasury at present in force should be suitably amended so as to allow dutiable goods to be put into bond.

CHEMICAL NOMENCLATURE.

RULES ADOPTED BY BRITISH AND AMERICAN COMMITTEES.

THE rules that have been adopted by the Nomenclature Committee of the Chemical Society of London and that of the American Chemical Society are as follows:—

1. In naming a compound so as to indicate that oxygen is replaced by sulphur the prefix *thio* and not *sulpho* should be used (sulpho denotes the group SO_3H); thus, HCNS, *thio*cyanic acid; H_3AsS_3, *thio*arsenic acid; $Na_2S_2O_3$, sodium *thio*sulphate; $CS(NH_2)_2$, *thio*urea. The only use of *thio* as a name for sulphur replacing hydrogen is in cases in which the sulphur serves as a link in compounds not suitably named as mecapto derivatives; thus; $H_2NC_6H_4SC_6H_4NH_2$, thiobisaniline. *Hyposulphurous acid*, not hydrosulphurous acid, should be used to designate $H_2S_2O_4$.

2. The word *hydroxide* should be used for a compound with OH and *hydrate* for a compound with H_2O. Thus, barium hydroxide, $Ba(OH)_2$, chlorine hydrate, $Cl_2.10H_2O$.

3. Salts of chloroplatinic acid are *choroplatinates* (not platinochlorides). Similarly salts of chloroauric acid are to be called *chloroaurates*.

4. Hydroxyl derivatives of hydrocarbons are to be given names ending in *—ol*, as glyce*rol*, resorcin*ol*, pinac*ol* (not pinacone), mannit*ol* (not mannite), pyrocatech*ol* (not pyrocatechin).

5. The names of the groups NH_2, NHR, NR_2, NH or NR should end in *—ido* only when they are substituents in an acid group, otherwise in *—ino*; thus, MeC(:NH)OEt, ethyl im*ido*acetate; $NH_2CH_2CH_2CO_2H$, β-am*ino*propionic acid (not am*ido*propionic acid); $NHPhCH_2CH_2CO_2H$, β-anil*ino*propionic acid; $CH_3C(:NH)CO_2H$, α-iminopropionic acid.

6. Hydroxy—, not oxy—, should be used in designating the hydroxyl group; as *hydroxy*acetic acid, $CH_2(OH)CO_2H$, not *oxy*acetic acid. *Keto*— is to be preferred to *oxy*— to designate oxygen in the group—CO—.

7. The term *ether* is to be used in the usual modern acceptation only and not as an equivalent of *ester*.

8. Salts of organic bases with hydrochloric acid should be called *hydrochlorides* (not hydrochlorates nor chlorhydrates). Similarly hydrobromide and hydriodide should be used.—*The Dyer and Calico Printer.*

Gas Residuals in 1922.—A return has been issued by the Board of Trade relating to the manufacture and supply of gas by 796 undertakings in Great Britain during 1922. The residuals amounted to 10,475,155 tons of coke and breeze, 169,770,531 gallons of tar, and 113,373 tons of sulphate of ammonia.

ITEMS OF INTEREST.

British Coal Output.—The output of coal for the week ended July 28 was 5,111,700 tons, compared with 4,601,000 tons in the preceding week and 4,989,100 tons a year ago.

Change of Address.—Messrs. P. and B. Evaporators, Ltd., announce that they have removed to larger premises at 75, Victoria Street, London, S.W. 1. Telephone number: Victoria 7482.

Tariff Notes.—As from August 21 the following duties on the importation of salt into Latvia are effective: On rock salt and salt in lumps, 0.02 lats. per kilog. gross; on ground salt, sea salt, and effervescing salts, 0.0275 lats.

Personal.—Dr. L. H. Baekeland, Honorary Professor of Chemical Engineering of Colombia University, has recently been made an Officer of the French Legion of Honour. Dr. Baekeland is known as the inventor of Velox and Bakelite. He is president of the Bakelite Corporation and of the General Bakelite Company.

Legal Intelligence.—At the meeting of creditors of Parker Ward and Co., manufacturing chemists, of Windsor House, Victoria Street, London, S.W., it was reported that liabilities amounted to £1,670., with total assets £206., and net assets £69. The liquidator stated that there was no likelihood of any dividend being paid to creditors.

Chemical Traders and Railway Rates.—The British Chemical and Dyestuff Traders' Association states that it has been given a seat on the Traders' Panel (London Area) which will be represented at the forthcoming meetings of the Railway Rates Tribunal. Members who desire to raise any cases of anomalies or instances of unfair classification are invited to send particulars to the Association.

Fuel Economy and "Meldrum" Furnaces.—We are informed by Messrs. Meldrums, Ltd., of Timperley, that during the month of July no fewer than fourteen orders for forced-draught furnaces and six for destructors were received. It is also stated that the fitting of the forced-draught furnace to water-tube boilers has met with considerable success. The trouble of smoke from hand-fired W.T. boilers has long been a serious drawback, but this difficulty, state the firm, can now be definitely overcome by the "Meldrum" improved smoke-consuming system.

Preservatives in Food.—Mr. Tankard, city analyst of Hull, reading a paper on Friday (August 3), before the Medical Officers' Congress, on chemical preservatives in food, said that his own investigations had convinced him that chemical substances were used to an extent that must be harmful. He recommended that the addition of any preservative other than sugar or salt should be prohibited except in the cases of cream, potted meats, potted fish and sausages, and that in these cases the only preservative permitted should be boric acid or its sodium salt in quantities not to exceed 14 grains per pound.

Dyestuffs' Licences.—The total number of applications received by the Licensing Committee during July was 371, of which 264 were from merchants and dealers. To these should be added the 24 cases outstanding on July 1, making a total for the month of 395. These were dealt with as follows: Granted 246, of which 227 were dealt with within seven days of receipt. Referred to British makers of similar products 70, of which 66 were dealt with within seven days of receipt. Referred to reparation supplies available, 50, all dealt with within two days of receipt. Outstanding on July 31, 29. Of the total of 395 applications received, 336, or 85 per cent., were dealt with within four days of receipt.

The Dyestuffs Act and the Irish Free State.—The British Chemical and Dyestuffs Traders' Association in their Bulletin dated August 7, state: We are officially informed that, for the time being, the Safeguarding of Industries Act and the Dyestuffs (Import Regulation) Act will continue to be enforced by the Free State Customs. It is, however, likely that both these measures will be repealed by the Government of that country. No official news can be obtained as to any intention to introduce other and similar legislation in their place, but it is thought that in the case of the Safeguarding of Industries an Act will be brought forward entailing somewhat similar duties. In the case of the Dyestuffs Act, there are rumours that the Free State Government intend to allow the free import of all dyes from *all* sources. The Free State authorities have promised to advise us at the earliest moment of any changes and decisions on these matters.

Platinum in Russia.—A Reuter message from Moscow states that a decree has been issued making platinum a State monopoly.

Belgian Coal Exports Stopped.—It is reported from Brussels that the Government has made an order strictly prohibiting the export of Belgian coal.

Wages in the Dyeing Trade.—In accordance with an agreement made on November 18, 1919, a reduction has taken place in the rates of wages of dyers and finishers, dating from August 1.

White Lead Convention.—Mr. G. Locker-Lampson, replying to a question in the House of Commons last week, said that the Home Secretary hoped to be able to announce the decision of the Government in regard to the ratification of the Draft Convention on white lead when the House reassembled next November.

Confiscated German Dyestuffs Stored.—It is reported that the French occupation authorities, who recently confiscated the stocks of dyestuffs found in the German plants taken over in consequence of the Ruhr occupation, have decided to hold back, for the time being, the sale of the dyes, as it is not the desire of the French to overload the market.

Midland Glass Trade.—The continued increase in the imports of glass, and particularly illuminating glass, from the Continent is causing anxiety to British makers. The competition is acute, and it would appear hopeless to compete in many of the low-grade lines. The trade in laboratory glass, which British manufacturers are able most satisfactorily to produce, is badly affected by the over-running of the market with cheap foreign products. Stocks of high and medium quality glass are lower, and it is confidently hoped that in the autumn there may be a revival in buying.

Proposed Factories for Sugar Beet.—It is stated that negotiations are in progress for the establishment of a new beet-sugar factory at Southwold, Suffolk. A local syndicate have provisionally secured a site near the harbour, and arrangements are now being made for the supply of the necessary quantity of raw material from firms in the district. At a meeting of the Hales Owen branch of the National Farmers' Union, held on Friday of last week, consideration was given in the proposal to establish a sugar-beet factory in Worcestershire, and a resolution approving of the scheme was passed.

Death from Motor Spirit Fumes.—An inquest was held at Liverpool on Wednesday on Robert Lloyd (47), labourer, who was one of three workmen employed at a spirit distillery in Bank Hall Lane, where a new motor spirit, "Discol," recently put on the market, is stored for distribution in the Liverpool area. The tank in which it was kept was observed to be leaking into a well beneath, and the three men were sent to clear the well out. After some time Lloyd was found lying on his back, whilst the other two appeared ill. Later Lloyd died in hospital, medical evidence ascribing the death to methyl-alcohol poisoning following inhalation. A verdict of accidental death was recorded.

New American Diabetes Treatment.—The American Chemical Society announces the discovery by J. A. Willaman, associate professor of biochemistry in the University of Minnesota, of a substance derived from plants and appearing to have the properties of insulin. This material, which has been named "glucokinin," is widespread in the plant world, but its active extract is best prepared from yeast by a method which took a good deal of working out. It is claimed that glucokinin is as effective as insulin, but is much cheaper and is much less toxic. Successful results have been obtained on dogs and rabbits, but clinical tests have not as yet been made on human beings.

Bleaching Barytes. — Considering the large barytes resources of this country, and, indeed, of the British Empire, it is astonishing that more is not done to make the country totally independent of foreign supplies. The removal of colour and extremely fine grinding are the factors essential for success, and neither present any serious technical difficulty. Beyond all other opportunities, at the moment, to create employment, the intensive production of high-grade barytes at home would seem to be the most promising. A very good process which is decidedly simple to operate has been brought to our notice recently. It is the invention of a British subject resident abroad, and is, we are informed, already at work in this country bleaching china clay. We shall be glad to put barytes producers in contact with the originator.

Margarine Manufacture in Germany.—It is reported that the German margarine works, which for a great part are controlled by Dutch concerns, have decided to quote their prices and sell their products in Dutch currency.

German Lime Trade.—Germany produced 4,354,000 tons of lime in 1922, according to a U.S. Commerce Report. Of this, 239,045 tons was consumed in the manufacture of cyanamide, 315,412 tons in other chemical industries, and 544,543 tons in agriculture. The chemical industries also consumed 123,068 tons of crude calcareous products.

Canadian Chemical Developments.—According to a Board of Trade report, a prominent company at Chippewa, near Niagara Falls, proposes to enlarge its electric furnace plant by adding a furnace building to be used exclusively for the manufacture of a carbide of silicon abrasive known as Crystolon. The development will cost about 165,000dols. and ensure a 25 per cent. increase in production of this line.

Cardiff as Oil Port.—It is stated that a start is to be made shortly in laying down an oil storage plant at Cardiff Docks. The plans provide for the construction of four huge tanks on a site owned by the Great Western Railway Company close to the entrance to the Queen Alexandra Docks. Two of these tanks will have a ten-thousand-ton capacity, and the other two half that quantity. A capital of £500,000. is involved in the scheme. It is hoped to establish a large refinery for treating the crude oil at Cardiff Docks.

National Gas Exhibition.—Included in the list of exhibitors at the National Gas Exhibition, 1923, are the following: British Uralite and Callactite Works, British Furnaces, Ltd., British Commercial Gas Association, British Sulphate of Ammonia Federation, Ltd., City of Birmingham Gas Department, Consett Iron Co., Cannon Ironfoundries, Ltd., Chemical Engineering and Wiltons Furnaces, Ltd., Canning, W. and Co., Ltd., Foster Instrument Co., Ltd., Holmes, W. C. and Co., Ltd., Jackson Boilers, Ltd., Midland Tar Distillers, South Staffordshire Mond Gas Co., Ltd., Shell Mex, Ltd., Thermal Syndicate, Ltd., Woodhall, Duckham and Jones, Ltd., and the Welsbach Light Co., Ltd.

War Office and Commercial Motor Vehicles.—It is officially announced that, with a view to encouraging the use in commerce of a 30cwt. lorry, fitted with giant pneumatic tyres, the War Office will pay a subsidy of £40. a year to all purchasers of approved vehicles or chassis of British manufacture who enrol under the scheme, which entitles the War Department to purchase such vehicles in a national emergency at a price fixed by the agreement at the date of enrolment. Specifications of approved vehicles will be supplied to interested manufacturers, and copies of the subsidy agreement may be obtained from the Secretary of the War Office, Imperial House (Room 37), Tothill Street, London, S.W. 1.

Government and the Dyestuffs Industry.—The Committee of Public Accounts, in a report issued last week, states that grants amounting to £135,919. in all have been made by way of assistance to the dyestuffs industry. These payments were made under the scheme for granting State assistance to the dyestuffs industry as explained in the White Paper presented to Parliament in November, 1918. The scheme contemplated the allocation of £2,000,000. over a period of three years, partly in loans, partly in contributions in aid of extensions of plant and buildings, and partly in grants in aid of research. The Committee are informed that the total expenditure under the scheme up to date has amounted to £426,000., and they understand that the balance will not be required. In addition to this expenditure on grants and loans, a sum of £1,700,000. was invested by the Board of Trade in British dyestuff manufacturing companies in 1919-20 and previous years. The dividend on these investments shown on the Appropriation Account, 1921-22, as received in that year was only £44,496., as compared with £89,250. shown in the estimate. In the estimates for 1922-23 and 1923-24 no dividend is shown in respect of these investments.

OUR BOOKSHELF.

Catalysis in Organic Chemistry. By Paul Sabatier. Translated by Professor T. Emmet Reid. London: The Library Press, Ltd., 26, Portugal Street, W.C. 2. Pp. 406. Price 25s. net.

Organic chemists will be indebted to Professor Reid for his careful and thorough translation of Professor Sabatier's classic work. The translator himself, at present professor of organic chemistry at John Hopkins University, Baltimore, U.S.A., has made several important contributions to our knowledge of catalytic hydrogenation, and was especially fitted to undertake the task, which he has carried through very successfully. The short account of Paul Sabatier's life and work, as given by the translator in the introduction, is of considerable interest. The first chapter of the volume deals with catalysis in general, and is followed immediately by a comprehensive chapter on catalysts, which is an excellent general summary. The third chapter, dealing with the mechanism of catalysis, is theoretical in nature, and an illuminating extension has been added by the translator in the form of a section on the theory of catalysis written by Professor W. D. Bancroft, chairman of the Committee on Catalysis of the American National Research Council. Coming to the detailed section, the work deals with isomerisation, polymerisation, etc., catalytic oxidations, various substitutions in molecules, and hydrations. The all-important section on catalytic hydrogenation occupies five chapters covering 262 pages, the use of nickel as catalyst occupying, as is inevitable, the greater part of this section. Catalytic dehydrogenation, dehydration, decomposition of acids and esters of organic acids, and the elimination of halogen acids or similar molecules, are all important sections. The concluding chapter deals with the decomposition and condensation of hydrocarbons, whilst a valuable practical chapter on the hydrogenation of liquid fats, inserted as a supplement, completes the volume. For the convenience of the reader, the translator has prepared a subject index of some 7,000 entries and an author index of about 1,100 names. As a reliable translation of a classic work in chemistry the volume will be welcomed. No claim has been made by the translator that the whole of the progress made in the subject since Sabatier completed his work has been added. Thus the important recent work of Armstrong and Hilditch on the mechanism of the catalytic hydrogenation of oils in the presence of nickel is not referred to at all.

A Treatise on Chemistry. By the Rt. Hon Sir H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S. New (sixth) edition completely revised by B. Mouat Jones and others. Vol. II., The Metals; Pts. I. and II. London, 1923: Macmillan and Co., Ltd. Pp. 1,564. Price 50s. net.

In the ten years that have elapsed since the publication of the fifth edition of this work, our knowledge of the chemistry of the metals and their compounds has greatly increased, and in our fundamental ideas of atomic and molecular structure, of valency, and of chemical affinity, and in the interpretation of the Periodic Law in particular, have great advances been made. As the amount of data that has been acquired in these newer branches of study is so enormous, the revisors have been well advised in not attempting to give a complete account of the new theories, but in maintaining the general style and character of the book. The introductory chapter on valency, the classification of the elements, atomic numbers, isotopes, atomic structure, and spectrum analysis, has been revised by Mr. L. J. Hudleston, and Mr. T. V. Barker has again dealt with the section on crystallography. Metals of Groups I. and II. have been brought up to date by Professor H. A. V. Briscoe; alkali manufacture by Professor J. R. Partington; groups III. and V. by Dr. H. F. V. Little; the rare earth metals and those of the titanium group by Professor J. F. Spencer; group VI. by Mr. A. A. Eldridge; the germanium group and manganese by Mr. C. R. Bury; group VIII. by Dr. O. R. Howell; while Professor C. O. Bannister has once more revised the metallurgical portions and Dr. Makower the section on the radioactive elements. For the purpose of convenience in handling and binding, the book has been divided into two separate volumes, but the pagination is continuous. Roscoe and Schorlemmer's treatise is too well known to demand either detailed criticism or review of contents. It occupies a unique position, in so much as it gives an encyclopædic survey of all the important facts and theories of inorganic chemistry in a manner which is at once attractive and conducive to easy reference. Possessing none of the formidableness, it is as comprehensive in vital facts as the majority of treatises of this type. This latest edition is excellently produced, and, to use the hackneyed phrase which best describes its worth, fully maintains the high traditions of the five previous editions.

PARLIAMENTARY NEWS.

Importation of Perfumed Spirits.

In the House of Commons on Tuesday, July 31, Sir W. Joynson-Hicks, replying to Mr. F. Gray, said: Under the general Customs law, perfumed spirits may be imported through the parcels and insured box posts, but not by sample or letter post. Such goods imported by the latter methods are liable to forfeiture and may be subjected to fines or returned to the country of export. The object of these provisions is to safeguard the revenue, and they are in accordance with the Regulations of the International Postal Union which are operative in all countries within the Union. Suitable action is taken by the Customs authorities in all cases of infringement brought to their notice.

Oil from Russia.

Sir P. Lloyd-Greame, replying to Captain Moreing, said: The imports of petroleum into the United Kingdom, consigned from Russia during the two years 1921 and 1922, amounted to 10,480,601 gallons, of which 9,081,555 gallons were from Batum and none from Novorossisk. I am unable to say how much of the petroleum was produced from wells owned or developed by English capital.

Merchandise Marks Bill.

Sir P. Lloyd-Greame, replying to Mr. Hannon, said: I regret that considerations of Parliamentary time have rendered it impossible up to the present to proceed with this measure. The question of a suitable time for the introduction of a Bill is at present under consideration, but I fear it will not be possible to proceed with it during the autumn session.

Sulphate of Ammonia.

Mr. Shinwell asked the President of the Board of Trade whether he is aware that sulphate of ammonia for export from the Clyde is not being weighed and checked, and that sealed samples are no longer taken; and whether, since this is contrary to custom, he proposes to take action in the matter?

Viscount Wolmer: The official control of the export of sulphate of ammonia, which was instituted during the war, is now at an end. The export is, accordingly, subject only to the ordinary Customs Regulations, and I have no reason to think that these regulations are not being observed. The hon. member appears to be referring to certain trade arrangements, over which the Board of Trade have no control.

Foreign Trade of the Irish Free State.

Mr. Hannon asked the President of the Board of Trade whether he is in a position to give the figures for the direct trade of the Irish Free State with countries other than Great Britain for the quarter ended June 30, 1923; whether any arrangement has been made with the Irish Free State for the publication of these figures, so necessary for accurate comparisons of the periodic movements of trade; and, if so, when the figures will be available?

Lieut-Colonel Buckley: It is understood to be the intention of the authorities of the Irish Free State to publish particulars of the trade between that State and other countries. I am not in a position to say when publication will begin.

Lead Poisoning in Industry.

Lord H. Cavendish-Bentinck asked the Home Secretary if his attention has been drawn to the high incidence of lead poisoning in electric accumulator works; if he is aware that the *Ministry of Labour Gazette* reports 14 cases in May and 22 in June; and whether, in view of the fact that strong regulations for the protection of workers in this occupation exist, he will consider the desirability of appointing additional inspectors to find out whether these regulations are being properly carried out and, if so, whether new regulations are required?

Mr. Bridgeman: Most of the cases in question (10 in May and 19 in June) were reported from two works at which there had been a sudden increase of orders and work had been carried on under conditions which, though not involving any breach of the regulations, were unsatisfactory. The matter has been taken up strongly with the firms, both of whom are re-organising the departments affected. The cases occurred mostly amongst workers newly engaged and, I am glad to learn, have not been serious in character. Apart from these cases, however, the Factory Department has for some time been dissatisfied with the results obtained under the existing regulations, and a special inquiry was commenced some time ago, with a view to ascertaining in what respects the regulations might require strengthening. This inquiry has now been completed and further action will be considered in the light of its results. No ground has arisen for the appointment of additional inspectors. The works in question have been regularly visited by the district staff, and a number of special visits have been paid by the technical officers engaged in the inquiry. The chief inspector is satisfied that the increase of lead poisoning cases in these works is not attributable in any way to any lack of inspection.

CORRESPONDENCE.

**** We do not hold ourselves responsible for the opinions expressed by our correspondents.*

CARBIDE PRODUCTION IN SOUTH AFRICA.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—Our attention has been called to a paragraph in your issue of July 27, headed "Carbide Production in South Africa." We would like to point out to you that the paragraph in question is not accurate in stating that the Rand Carbide, Ltd., is the present sole manufacturer of carbide in South Africa. The South African Carbide and By-products Co., Ltd., owns a factory at Ballengeich, Natal, which was completed early in 1922. It is equipped with all the most modern and up-to-date plant for the manufacture of calcium carbide, including its own power-station, and is designed for an output of some 4,000 tons per annum.—Yours, etc.,

Thomas Ogden, Secretary,
South African Carbide and By-products Company, Ltd.
13, St. Helen's Place,
London, E.C. 3,
August 1, 1923.

SOUTH WALES NOTES.

[Specially Contributed.]

Owing to the scarcity of orders for forward delivery the majority of the tinplate works ceased work for the full week, and in some cases a little longer. There is a general idea that this industry will meet with much improvement in the near future, however, and the stabilisation of selling prices has a very steady effect upon the market. Patent fuel makers find new business rather quiet, and owing to the better supply of small coals are accepting somewhat lower figures. Some of the factories were on stop only for two days. Cokes are again in strong demand, and important inquiries from Belgium and Germany for supplies over the remaining portion of the year have been received. By-products are selling very well and the outlook is considered good. Among the imports to Cardiff were 920 gallons acetic acid from Rotterdam; Swansea imports included 26 tons zinc ashes from Nantes, 3 tons calcium carbide from Dalmatia, 998 tons iron pyrites from Pomaron, and 19cwt. soda ash from Haugesund. The exports included 5 tons dynamite to La Jueira from Cardiff.

The Manufacture of Portland Cement from Marl.—By Raymond E. Kirk. Bulletin No. 2 of the Engineering Experiment Station of the University of Minnesota, Minneapolis.

"Tolerances" on Chemical Specifications.—Pamphlet No. 50, issued for the British Chemical Standards Movement, by Messrs. Ridsdale and Co., 3, Wilson Street, Middlesbrough.

FERTILISER NEWS.

Nitrate of Soda.—Signs are not wanting, apart from the flight of the German mark, quoted at the time of writing, at 25 million to the £ sterling, that affairs in Europe are rapidly approaching a crisis. The situation, therefore, so far as nitrate of soda is concerned is of great interest, for it is difficult to foresee what effect the currency collapse in Germany may have. As things are at present, of course, the chaotic state of most of the continental exchanges precludes business of any large dimensions, and the nitrate market is very quiet. Already there is talk of the repudiation of the German currency, and the substitution of a stabilised and rational medium of exchange, which, if accompanied by a sufficiently powerful Government, might result in the re-entry of Germany as a purchaser of Chilean nitrate. This however, is but a remote possibility, and it is more likely that, so far from there being an improved demand for the Chilean fertiliser, there will be a piling up of stocks consequent on the very heavy shipments now being made to Europe and Egypt. The market in the United States is nothing like as promising as it was during last season, so that producers are looking more in this direction for further orders. The past month was disappointing in the paucity of inquiry, the Association having booked orders to the extent of 13,000 or 14,000 tons only, bringing the total sales for the current season up to about 900,000 tons. With reference to the statistics for July, it is now ascertained that actual shipments of nitrate from Chile during the month exceed the estimated figures dealt with in this column last week, and the cabled corrections show the quota for Europe to be 99,000 tons, for the United States, 71,000 tons, and for other countries not separately specified, 24,000 tons. The altered figure for exports, therefore, amounts to 194,000 tons, compared with the 171,000 tons previously estimated. A compensating fact in this connection, however, is that the production total for June has also been amended from 153,000 tons to 166,0000 tons, and when it is remembered that production is being steadily increased, it may be taken for granted that the present estimated figure of 162,000 tons for July will be rather short of the mark. This being so, the heavy stocks on the West Coast are not likely to be below the million ton figure spoken of last week.

Sulphate of Ammonia.—Despite the comparatively heavy exportation of this fertiliser during the first half of the year, the greatly increased production consequent on the activity in the iron and steel industries has led to the formation of considerable stocks. In order to work off these stocks, and taking advantage of the excellent harvest prospects in this country, it has been decided to reduce prices. Accordingly, the Sulphate of Ammonia Federation have lowered the quotation for 25¾ per cent. neutral material by 10s. per ton to £14. 5s. until the 18th inst. After that date, and until the end of September, the official price will be £14. 10s., the conditions of sale being identical with those affecting the last reduction in prices. As is only just, the Federation are refunding to buyers who have already purchased sulphate at the previously announced rates, the difference of 10s. per ton. It is declared that no further reduction in the prices for home consumers will be made, on the contrary, the usual practice of following a gradually rising scale will be adhered to. This further effort to secure the goodwill and custom of the home farmer should meet with success at a time when the prospects for British agriculture are better than for many months past. Certain it is that if the superior fertilising value of sulphate over any other nitrogenous fertiliser at present prices was only fully realised by the ultimate consumer, the home demand would become more active than ever. Production in America continues on a large scale, but most of the output is going into consumption, domestic buyers having contracted for almost the entire quantity. The labour troubles of last year not only curtailed exportation during the earlier part of the current year, but reduced stocks to vanishing point, so that up to the present time, the surplus available for export has been very small. Small quantities have gone abroad, it is true, but at a price which gives the British product a considerable advantage. In Japan, the situation is not at all clear, and the market now has a tendency to be sluggish. A correspondent in Osaka informs us that under the influence of the heavy decline in the raw-silk market, the demand for nitrogenous fertilisers has decreased considerably, while material bought early in the year at higher prices is now arriving, and tending to weaken the market. The Japanese product was quoted at 200 yen per ton towards the end of June, while foreign material due to arrive was much lower at about 185 yen. Under these conditions, consumers are awaiting further developments.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

It is satisfactory that while the iron, steel, and iron-ore industries on the North-west coast are depressed, and even the coal trade has become duller, the coke industry maintains the activity which it has exhibited during the past three months. So far, however, there has been no shading of coal prices, and it is difficult to see how any concession can be granted, except under the stress of severe competition, as it is notorious that the losses being sustained by the Cumberland collieries are still very large. Some diminution in the requirements is due to the closing down of so many iron ore mines, and that in turn has been caused by the smelting of a smaller tonnage of iron and the rolling of less railway material. It is almost impossible to estimate prospects in the iron trade, though it should be stated that there is now a feeling that the present production can be maintained and that possibly some improvement may be witnessed before the middle of October. What is wanted above everything else is a revival in the steel trade, for when the rail mills are working the local consumption of ordinary iron, in the smelting of which the local coke is used, is very large. Activity at the merchant plants has not the same value for the coke trade as at the furnaces making for the steelworks. In all the circumstances, therefore, the position as it concerns the coking industry is far from being unsatisfactory. The plants at Oughterside, Flimby, Allerdale, Lowca, and St. Helens are all getting rid of their output, and most of it, too, to the furnaces in West Cumberland, at 29s. to 33s., according to carbon content. There is a good inquiry from the Continent, at 34s. to 40s. per ton, f.o.b., and parcels are being shipped regularly to Hamburg and Antwerp. The Continental trade is very valuable at this present juncture, and the expectations are that it will be at command for a few months longer. Residuals are a fair trade. The whole of the tar is going to the chemical works. Crude benzol is in steady demand, and the make of sulphate of ammonia is being absorbed. Road tar is quiet. East Coast coke supplies this week are 8,100 tons.

THIRTY-FIVE YEARS AGO.

(From the "Chemical Trade Journal," August 11, 1888.)

A New Industry for Widnes.—Residents in Widnes will be pleased to hear that they are within measurable distance, not of the annihilation of waste heaps, but of their decrease, and at the same time the manufacturers are to be congratulated in the almost certain success which must necessarily follow, from their attempts to turn the alkali waste into gold. Some time ago we referred to Chance's process for extracting the sulphur from alkali waste, which left a residue of carbonate of lime still to be deposited somewhere. We pointed out at the time that this residuum was the safety-valve of the Leblanc process, whereby all impurities were let out, and it was folly to think of ever using it over and over again in the process of making black-ash balls. A new solution has been found for the problem, which is being energetically acted upon. It has been found that the residue from Chance's sulphur recovery process, and also the lime sludge from the manufacture of caustic soda, are most suitable materials for the manufacture of a high-class Portland cement, and a company with £150,000. capital is in course of formation to erect works with this object in view in the town of Widnes. It is projected to build the works on waste land adjoining the river and having easy access to the Ship Canal, in the construction of which enormous quantities of cement must necessarily be used. In all probability the new works will receive the caustic sludge and the Chance waste from those alkali works using a process, several works being now busy erecting the new plant, and, in addition, will be in a position to grant licences to use, to other manufacturers situated at a distance. After years of trade depression through which the town has passed, it is encouraging to see a prospect of satisfactorily turning waste to profitable account, and establishing an industry which will give employment to so many hands.

REPORTS OF COMPANIES.

J. and J. Cunningham, Ltd.

The profits for the year to June 30 last were well maintained, the net surplus at £21,700, comparing with £21,400, for the previous year, while, including the sum brought in, the disposable balance is £1,700, higher at £42,900. As for each of the two preceding years the dividend on the ordinary shares is 5 per cent., free of tax, and the balance of £22,900, is carried forward, as compared with £21,200, brought in. In addition to a reserve fund of £35,000., there is a works reserve of £40,000, and a special reserve fund for preference dividend of £18,000., making total reserves £93,000.

Diamond Match Company.

Statement for six months to June 30 shows gross profit $2,251,427. Deducting State and city taxes, $170,478., depreciation and amortisation, etc., $584,570., insurance reserve, $100,000., interest on deferred timber payment, $29,343., and bond interest, discount, and premium, $289,701., leaves net profits $1,077,334. Reserve for Federal taxes absorbs $173,602., leaving $903,732, plus balance brought in, making $4,616,082. Deducting dividends, $678,604., leaves balance at June 30 $3,937,478.

DIVIDENDS.

Broken Hill Proprietary Co., Ltd.—Net loss for the year ending May 31, 1923, £106,086. 0s. 11d., after allowing for depreciation £155,304., and £131,277. debenture interest.

W. T. Henley's Telegraph Works Co., Ltd.—Dividend on preference shares at rate of 4½ per cent. per annum, less tax, for half-year to June 30 last; also interim dividend on ordinary of 1s. per share, less tax.

Dublin and Wicklow Manure Co., Ltd.—Preference dividend and dividend of 2½ per cent. on ordinary for year ended June 30, 1923.

United Turkey Red Co., Ltd.—It is proposed to pay the arrears of preference dividend up to date.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

Australia.

A manufacturers' agent in Sydney desires to be placed in communication with British manufacturers of drugs and chemists' sundries. He wishes appointment, on a commission basis, for Australia, and is said to have a good connection among wholesale chemists throughout the Commonwealth. (Ref. No. 126.)

Barbados.

A commission agent in Barbados, who already represents some British manufacturers of fertilisers, etc., desires to secure the representation for Barbados of British exporters of lard-compound, matches, etc. (Ref. No. 134.)

Argentina.

A firm in Buenos Aires, with headquarters in Asuncion (Paraguay), wish to obtain connections with British importers of essence of petit grain, etc. (Ref. No. 158.)

NEW COMPANIES.

Lintox, Ltd.—Capital £100. Manufacturers of and dealers in chemicals and chemical preparations, etc. Office: 36, King Street, Cheapside, E.C.

Pattison's Combustion Product Plant, Ltd.—Capital £15,000., in 12,000 6 per cent. cum. part pref. shares of £1., and 30,000 ordinary shares of 2s. Director: C. M. Pattison, Cefn-Coed, Merthyr Tydfil.

Coxeter and Son, Ltd.—Private company. Capital £8,000., in 7,000 preference shares of £1. and 20,000 deferred shares of 1s. Manufacturers of and dealers in scientific instruments and apparatus, etc. Office: 171-175, Pancras Road, N.W. 1.

Ellis and Sons (1923), Ltd.—Private company. Capital £20,100. To acquire any secret or other information, process, or formula in respect of or in connection with the utilisation of waste materials, etc. H. A. King (managing director), 7, Cyprus Avenue, Finchley, N. 3.

Kirkland Iron Ore Co., Ltd.—Private company. Capital £5,000. Office: Bank Chambers, Lowther Street, Whitehaven.

Waipuna Kauri Gum Co., Ltd.—Private company. Capital £90,000., £1. shares (60,000 10 per cent. non-cum. preferred ordinary and 30,000 ordinary). Office: Winchester House, Old Broad Street, E.C.

Houston and Wallace, Ltd.—Private company. Capital £4,000. Oil and fat refiners. Office: 183, West George Street, Glasgow.

GAZETTE NEWS.

MORTGAGES AND CHARGES.

Cambrian Electrolytic Zinc Company, Ltd., London, E.C.—Registered July 19, £10,000. debs. (filed under sec. 93 (3) of the Companies (Consolidation) Act, 1908), present issue £3,000.

Cellulose Holdings and Investment Company, Ltd., London, E.C.—Registered July 16, Trust Deed dated June 28, 1923 (supplemental to Trust Deed dated October 18, 1922), securing £750,000. deb. stock (including £500,000. secured by original deed), and premium of 20 per cent. on redemption.

Central Cornwall China Clay Company, Ltd., St. Blazey.—Registered July 20, £3,200. debs., part of £25,000.

Chemical Engineering and Wilton's Patent Furnace Company, Ltd., London, S.W.—Registered July 12, £3,000. debs. (filed under sec. 93 (3) of the Companies (Consolidation) Act, 1908), present issue £2,000.; also registered July 20, £500. debs. part of £3,000.

Hydrogen, Oxygen and Plant Company, Ltd., London, E.C.—Registered July 13, £35,000. 2nd debs. (filed under sec. 93 (3) of the Companies (Consolidation) Act, 1908), present issue £14,800.

Manufacturing Concrete Works, Ltd., London, S.W.—Registered July 16, £5,000. debs.

Sydbie, Ltd., London, E.C., glass manufacturers.—Registered July 18, £5,300. deb., to Baron Somers, Eastnor Castle, near Ledbury.

Tidy Betty, Ltd., Leeds, stove polish manufacturers.—Registered July 17, £1,250 deb., to J. H. Broughton, Ferrybridge.

Western Laboratories, Ltd., London, W., celluloid manufacturers.—Registered July 14, £350. mort., to Cheltenham and Gloucester Building Society.

SATISFACTIONS.

Marley Hill Chemical Company, Ltd.—Satisfaction registered July 24, £2,500., part of amount registered January 4, 1921.

LIMITED COMPANIES. — Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions; Orders; and Official and Other Notices.

Degreasing Company, Ltd., Dewsbury.—Resolved June 28, confirmed July 20, that the company be voluntarily wound up. W. H. Shaw, Market Place, Dewsbury, liquidator.

North of Ireland Chemical Company, Ltd.—Meeting of creditors held at R. Bell's, 2, Wellington Place, Belfast, on August 1. N.B.—This meeting was called to comply with the provisions of the Companies (Consolidation) Act, 1908, and was a formal meeting, as all creditors have been or will be paid in full, consequent on the acquisition of the company's business by the Belfast Corporation.

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

Grice, H., Westlyn, Quarry Bank; analyst; £51. 18s. June 11.

Hutchinson, J. A., Holton Chemical Works, Bolton; chemical manufacturer; £11. 3s. June 20.

THE PATENT LIST.

APPLICATIONS FOR BRITISH LETTERS PATENT.

July 23 to 28 (inclusive).

Film Mills for Emulsification of Liquids, etc., and for Grinding Coal, Pitch, etc. Barradell, L.; Carter, Ltd., J. H.; and May, C. 19,142.
Vulcanisation of Caoutchouc. British Dyestuffs Corporation, Ltd.; Hailwood, A. J.; and Lefebure, V. 19,197.
Soaking Liquors for Dried Hides. British Leather Manufacturers' Research Association; Lloyd, D. J.; and Pickard, R. H. 19,312.
Acid-resisting Cements. Calder, W. A. S.; Chance and Hunt, Ltd.; Gidden, W .T.; and Maudsley, R. T. 19,223.
Vulcanisation of Caoutchouc. Chatelan, J. 19,311.
Centrifugal Separators for Dehydrating Oil. De Laval Chadburn Co., Ltd.; and Johnstone, H. 19,091.
Treatment of Ammonium Chloride Lyes in Iron Vessels. Henkel et Cie.; and Weber, W. 19,218.
Desulphurising Shale Distillates. Hocking, C. M. 18,988.
Production of Argon. Jackson, W. J. Mellersh-. (*Soc. l'Air Liquide Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude*). 18,911.
Distillation of Coal. Jones, F. W. Salisbury-. 18,899.
Dyeing Cellulose Acetate. Kilby, W.; and Morton Sundour Fabrics, Ltd. 19,261.
Extracting Tars and Gases from Bitumen-containing Materials. Klötzer, M. 18,947.
Apparatus for Elevating Liquids. Knight, H. M. 19,190.
Viscose. Lilienfeld, L. 19,027.
Nitrate of Potassium. Michael and Co., J. 19,229.
Tanning Extract. Moeller, W. 19,294.
Non-peroxidising Ether. Naamlooze Vennootschap Nederlandsche Gisten Spiritus Fabriek. 19,012.
Chemically Pure, Toxic Free, Narcotising Ether. Naamlooze Vennootschap Nederlandsche Gisten Spiritus Fabriek. 19,026.
Acid-proof Articles from Diatomic Earth. Ohlsen, J. U. A. 19,071.
Bauxite Cements. Patrouilleau, L. G. 18,940.
Separation of Solids from Liquids. Peet, R. F. O'D. 19,256.
Vulcanisation of Rubber. Pirelli and Co. 19,225.
Dyeing. Plauson's (Parent Co.), Ltd. (*Plauson*). 19,067.
Condensation Products. Pollak, F. 18,929.
Phosphorescence in Luminous Paints. Risler, J. 19,333.
Separating Particles of Metal from a Mixture. Schmidt, K. 19,208.
Cooling Gases During Condensation. Schmied, W. 19,170.
Cooling Incandescent Coke. Sulzer Brothers, Ltd. 18,896.

COMPLETE SPECIFICATIONS ACCEPTED.

Readers desiring to peruse any of the following specifications in the original can obtain a copy by sending 1s. in stamps to the Comptroller, Patent Office Sales Branch, 25, Southampton Buildings, Chancery Lane, W.C.

1922.

Titanium Compounds. Llewellyn, W. B.; Spence, H.; and Spence and Sons, Ltd., P. 1,413. **200,848**
Anthraquinone Sulphonic Acids. Thomas J.; and Scottish Dyes, Ltd. 1,575. **200,851**
Treating Ores and Concentrates to Convert them into Sulphates. Read, J. B.; and Coolbaugh, M. F. 1,577. **200,852**
Vulcanisation of Rubber. Naugatuck Chemical Co. 1,594. **180,978**
Prevention of Evaporation of Stored Liquids. Wade, H. (*Standard Oil Co.*). 2,436. **200,855**
Dyeing and Printing Acetyl-silk. Green, A. G.; Saunders, K. H.; and British Dyestuffs Corporation, Ltd. 7,980. **200,873**
Treating Cellulose Acetate before Dyeing. Soc. Chimique des Usines Du Rhone. 10,991. **192,994**
Cyanides. Marks, E. C. R. (*Du Pont de Nemours and Co., E. I.*) 11,022. **200,902**
Abrasive and Fire-resting Material. Bourdeau, L. E. 11,039. **200,903**
Bringing Liquids and Gases into Contact. Soc. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploitation des Procédés G. Claude. 11,169. **178,852**
Plastic Materials. British Cellulose and Chemical Manufacturing Co., Ltd.; Small, F. T.; and Dickie, W. A. 11,257. **200,922**
Continuous Dehydration and Distillation of Tar or Oils. Wilton, T. O. 11,486. **200,933**
Removal of Chlorides from Milk. Puglia, Dr. J. and Meunier, C. 11,489. **179,919**
Drying Coal. Steen, T. 11,718. **200,937**
Dyes and Stains from Xanthorrhœa Gums. Moulder, C. H.; and Gulley, F. P. 11,990. **200,942**
Protection of Copper and Its Alloys from Oxidation or Corrosion. Muntz, Sir G. A. 12,040. **200,944**
Packing or Filling Material for Reaction Chambers, Towers, Absorption Chambers, and the Like. Schaefer, C. 12,516. **200,956**
Extraction of Oils or Fats from Oleaginous Vegetable Matter. Cellulose et Papiers, Soc. de Recherches et d'Applications. 12,952. **179,931**
Formic Aldehyde. Heinemann, A. 13,340. **179,951**
Tanning Process. Lauro, A. G. 15,575. **200,979**
Treating Substances Liable to Oxidation by the Action of Air. Moureu, C.; and Dufraisse, C. 15,482. **181,365**
Priming Compositions. Rathsburg, Dr. H. 18,060. **201,009**
Aromatic Aldehydes. Barrett Co. 28,836. **189,107**
Calcium Salt of Acetyl Salicylic Acid. Soc. Chimique des Usines du Rhône. 31,384. **190,123**

1923.

Washing Sand. Peebles, J. 1,392. **201,108**
Artificial Resins. Holzverkohlungs-Industrie Akt.-Ges. 8,750. **196,265**
Automatically Emptying Mixing-machines Having Pans with Rotating Bottoms. Baker, Sons, and Perkins, Ltd., J.; and Soc. Anon. des Anciens Etablissements A. Savy Jeanjean et Cie. 5,865. **195,601**

COMPLETE SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

1922.

Separating the Vapours of Volatile Liquids from Gases. Bregeat, J. H. 25,711. **201,119**
Evaporating, Concentrating, Distilling, or Like Apparatus. Soc. des Condenseurs Delas. 28,971. **201,123**

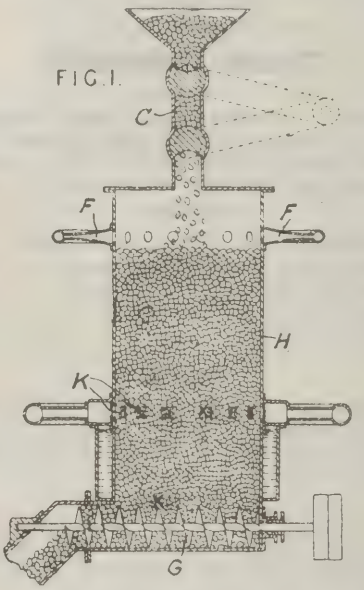
1923.

Calcium Oxalate from Trees. Bhopal Produce Trust, Ltd. 1,774. **201,131**
Evaporating-apparatus. Lillie, S. M. 4,239. **201,134**
New Azo-dyes. Farbenfabriken vorm. F. Bayer and Co. 15,548. **201,150**
Highly Active Charcoal. Farbwerke vorm. Meister, Lucius, and Brüning. 18,092. **201,163**

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Distillation Plant. Plauson's (Parent Co.), Ltd., London. (H. Plauson, Hamburg, Germany.) British Patent, **198,705**, of 1921.

Oils, bitumens and resins are obtained from shale, oil-bearing sands, bleaching earths, peat, lignite, coal or wood, by effecting distillation of the materials in a current of steam or inert gas such as carbon dioxide moving at a high velocity of the order of 100 metres per second and upwards. The temperature is below the ordinary temperature of decomposition of the materials. A small quantity of solvent such as benzine, benzol, etc., may be added to the steam or inert gas. The material, for example, oil shale, may be passed down a vertical cylinder H, Fig. 1, from a feed device C to a discharge-worm G. Steam which may be superheated to



about 350° C. and under a pressure of 3.5 atmospheres is fed through a ring-shaped device having nozzles F such as are used in steam turbines, and expands to form a stream moving at about 500 metres per sec. Steam and entrained matters pass away through slits K, protected by wire netting. The lower part of the cylinder H is surrounded by a cooling-jacket in which water is preheated for use as boiler feed. A horizontal cylinder through which the material is fed by a worm, may be used. Steam is supplied through a single nozzle near the outlet, and passes with the material from the outlet. Bituminous coal yields a product containing Montan wax and a petroleum jelly. In treating peat at 375-400° C., tar oils, wax, methyl alcohol, acetic acid and acetone are obtained. In treating roots and resinous woods under vacuum at about 220° C., turpentine, resin and a small amount of resin oil are obtained. The wood may be afterwards treated with steam at about 300-380° C. to yield methyl alcohol, acetic acid, acetone and tar oils.

Preserving Wood. W. Carpmael, London. (Chemische Fabriken vorm. Weiler-ter Meer, Uerdingen, Germany.) British Patent, **198,825,** of 1922.

Wood is impregnated with a composition comprising an inorganic salt, an organic nitro-compound, and a basic or other compound of a bivalent metal of the ammonium sulphide group—namely, zinc, manganese, nickel and cobalt. In examples, sodium fluoride, sodium sulphate, and magnesium chloride; dinitrophenol, sodium dinitrophenate, dinitro-o-cresol, and basilite (a mixture of anilinedinitrophenate and sodium fluoride); zinc oxide, zinc carbonate, zinc sulphate, and nickel carbonate, are specified.

Electrolytic Production of Glyoxylic Acid. E. C. R. Marks. London. (Royal Baking Powder Co., New York, U.S.A.) British Patent, **198,855,** of 1922.

In apparatus of the type in which the cathode is constituted by a film of mercury supported by diaphragms 35, Fig. 3, the electrolyte is introduced through a series of openings 58 in conduits 56, 57 so as to impinge against the outer edges of the diaphragms, and flows to a central space between the diaphragms whence it is led away by a pipe 59. Each diaphragm is provided with a central depression 41, Fig. 4, housing a spider 42 at the end of an electric connection 43 enclosed in a glass or porcelain tube 44. A number of diaphragms are arranged the length of the cell and are supported by shoulders on insertions 38 in the walls 15 and at their contiguous rims by transverse members.

FIG.3.

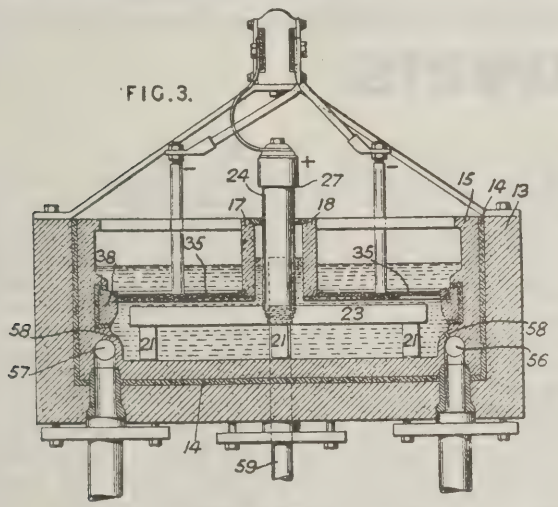


FIG.4.

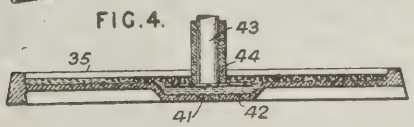

Slabs 17, 18 of slate or other insulating material running the length of the cell and forming the central chamber, are supported at the ends by standards. Graphite or other anodes 23 are supported by blocks 21 and are provided with connecting members 24 passing through a cover 27. The spent electrolyte is led to a regenerating vat from which it is pumped back to the conduits 56, 57; the vat is provided with a gas discharge pipe. Chambers in communication with the space above the cathodes are provided at opposite ends of the cell, one of which is provided with porcelain or stoneware paddle to circulate the liquid and the other with a discharge pipe. The discharge pipe is connected to a vat where the substance to be acted upon by the amalgam is added. The regenerated liquid is pumped to a cooling tank whence it passes to the paddle chamber. The vessel 15 is of stoneware and is separated by a layer 14 of cement from an outer vessel 13 of reinforced concrete. The apparatus is suitable for the conversion of oxalic acid into glyoxylic acid. An electrolyte of sodium chloride solution is used, and a little hydrochloric acid is added to the oxalic acid.

Tanned Rubber. C. Marter, London. British Patent, **198,914,** of 1922.

India-rubber in a plastic state is heated with tanning agents such as extract of hemlock, oak, chestnut, etc., and is rolled into sheets or otherwise shaped to produce a material having the appearance, and most of the properties of leather. The tanned rubber is slightly plastic and is soluble in most of the usual solvents for rubber. Colouring, filling, etc., materials, fats, oils, etc., may be added before, during or after treatment with the tanning agent. The material may be rendered fireproof by soaking it in a solution of protochloride of tin, and may be made tougher, and more porous by treatment with alum solution.

Azo Dyestuffs. W. Carpmael, London. (Farbenfabriken vorm. F. Bayer and Co., Leverkusen, Germany.) British Patent, **198,634,** of 1922.

Disazo dyes are prepared by coupling the tetrazo compound from 4:4¹-diamino diphenyl-3:3¹-dicarboxylic acid on the one hand with an aryl-2-naphthylamine, and on the other with an azo dye component which contains a sulphonic or carboxylic group, or two hydroxy or two amino groups, or one hydroxy and one amino group or a hydroxy group in conjunction with the $CH_2.CO$ group of the acetoacetic-anilide or of the pyrazolones. The products dye cotton in red to blue shades which by after-treatment with metallic salts, for example copper or vanadium salts, become deeper and fast to light and washing. In an example the tetrazo compound is coupled with phenyl-2-naphthylamine and 1-amino-8-naphthol-4-sulphonic acid.

Asbestos in Pottery Manufacture. J. E. Tams, Stoke-on-Trent. British Patent, **198,607,** of 1922.

A transparent body similar to china, felspar, or parian consists of powdered asbestos and powdered frit produced from powdered asbestos and soda fretted in the usual way and ground. China clay, felspar, or stone may be added.

Removing Ink from Printed Papers. P. Bourcet, and H. Regnault, Paris. British Patent, **198,854,** of 1922.

In removing ink from printed paper, in the recovery of pulp for paper making, the paper is pulped, and the oily constituent of the ink is removed by treating the pulped paper at 50° to 100° C., for about 1 hour, with an emulsion of oleic or other liquid fatty acid in an aqueous solution of sodium sulpho-ricinate or other alkaline salt of a sulphated oil such as sulpho-oleic, sulpho-ricinic or sulpho-resinic acid. An emulsion of oleic acid and alkaline oleate may be used. Toluene, xylene, or other volatile hydrocarbons or other liquids of lower density than, and not miscible with, water are added together with tepid water, and the mass agitated, when the carbon and pigments are separated from the pulp and absorbed. For separating the liquids, high speed centrifugal filters are used, the pulp being retained and the water and hydrocarbon driven out. The hydrocarbon is recovered by distillation.

Purifying Fats. F. Bedford, York. British Patent, **198,706,** of 1921.

Fats and fatty oils are purified by treatment with an alkaline solution of a neutralising agent capable of giving off oxygen or of a neutralising agent and an oxygen carrier, manganese compounds excepted. Aqueous solutions specified are those of (1) sodium peroxide or percarbonate to which sodium hydrate, hydrogen peroxide, or both may be added; (2) hydrogen peroxide and caustic soda. Examples are given of the treatment of cottonseed oil at 16° C. with a 10 per cent. solution of sodium peroxide, and of hot-pressed sesame oil at 22° C. with a solution of caustic soda of 20° Bé. mixed with a solution of sodium peroxide.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Chromium Sulphate. O. Nydegger, Mornimont, Belgium. British Patent, **198,645.** Convention date, May 31, 1922.

Iron is separated from the solutions of chromium and ferric sulphates obtained by treating chromite with chromic and sulphuric acids, by adding an alkali sulphate, such as ammonium sulphate, and concentrating the solution until the boiling-point reaches 150° C. A double salt such as ammonium ferric sulphate separates out and is removed. The excess of acid remaining is neutralised with lime, leaving a solution of normal or basic chromium sulphate. The double salt may be treated with lime or soda to recover the alkali sulphate.

Soaps. Hohenloher Seifenfabriken Akt.-Ges., Augsburg, Germany. British Patent, **198,681.** Convention date, June 1, 1922.

Soaps for use with hard water are provided with a proportion of insoluble metal combinations of a feebly basic character, such as oxides or hydroxides of magnesium, calcium, barium, aluminium or zinc, which precipitate the hardness-causing salts as a loose powder. Conveniently a water-soluble salt such as magnesium sulphate is added to the soap ingredients before or during saponification, alkali in sufficient excess to decompose the salt being used. The proportion per 100 parts fatty acid may be one part of magnesium sulphate for each degree of hardness of the water; 40 parts is specified.

Control of Sulphuric-acid Manufacture. Aktieselskab Dansk Svovlsyre- and Super Phosphat-Fabrik, and Dansk Aktieselskab Siemens Schuckert, both in Copenhagen. British Patent **199,004.** Convention date, June 9, 1922.

The rate at which the oxidising agent is fed to the reaction in the production of sulphuric acid in chamber, tower, or like apparatus is controlled by the difference of temperature between the gases when leaving and when entering the plant, or the difference between the temperatures of the first and last chambers or towers. These temperatures are measured by electrical thermometers which are connected through suitable resistances with a galvanometer and battery in the manner of a Wheatstone bridge arrangement so that the difference of temperature is measured by the galvanometer deflection. The zero of the galvanometer scale is arranged to indicate the desired difference of temperature, and two adjustable contacts are arranged on the scale on either side of the zero so that the pointer of the galvanometer on reaching these contacts will make or break a circuit controlling the cock which admits the oxidising agent, the distance of the contacts from the zero corresponding with the permissible fluctuation of the temperature difference. It is stated that this controlling apparatus may be connected with more than one apparatus for admitting the oxidising agents, for instance, in such a way that these are controlled simultaneously or one after the other; or it may be arranged to control two or more admission apparatus for two or more first chambers; or it may control only a part of the total supply of oxidising agent, the rest being admitted by an apparatus not automatically controlled.

Ceramic Material. W. Green, Northallerton, Yorkshire. British Patent, **198,817,** of 1922.

A ceramic material is made by incorporating hard porcelain ingredients containing potash, etc., with a sintered irreducible oxide such as pure alumina or zirconia of a high melting point. The composition is fired at a high temperature to produce a hard tough product having a low electric conductivity and a low porosity. The composition may consist of alumina, potash felspar, china clay, and ground flint. Cores which resist the action of liquid or gaseous mercury may be made from the composition.

MARKET REPORTS.

LONDON "OPEN MARKET" REPORT. Wednesday.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals.—Over the holidays business has been more or less at a standstill. The little passing has been confined to purchases of smallish spot lots. The European political situation is naturally having a bad effect on trade generally. **Acetic Acid,** 80% technical, £47. to £48.; 80% pure, £50.; 98% glacial, £60. in casks and £75. in glass demi-johns, ex wharf, London; this market remains firm with business dull. **Acetone,** British Government specification, about £125. to £130. per ton; owing to acute scarcity of spot supplies and at the same time an active demand, this product is very firm; the prices quoted are nominal; further advances are expected. **Arsenic,** Cornish, white powdered, about £72. to £73. per ton, for spot parcels; there has been little demand for the material on offer. **Alum,** lump, £10 to £10. 10s. per ton, in casks; last week's cheaper prices from dealers have not brought any improvement in demand. **Anhydrous Ammonia,** 99.95%, 1s. 5d. per lb.; at this quoted rate the market is easy and remains dull. **Barium Chloride,** 98/100%, £15. to £15. 5s. per ton, on spot; business is very limited indeed; dealers quoting at these rates. **Bleaching Powder,** 35/37%, £10. to £10. 10s. per ton; continental material offered by dealers at these figures is very slow in being taken up. **Borax,** commercial, granulated, £26. 10s.; crystals, £27.; powdered, £28.; extra fine, £29.; B.P., crystals, £31.; powdered, £32.; extra fine, £33. per ton, for home trade only, in 2cwt. free bags, carriage paid to destination; British makers offering at these unchanged rates; prices for export vary as to destination; importers are offering for home consumption under similar conditions at—granulated £25. 10s., and powdered £27. per ton. **Borax Glass,** lump, £74.; powdered, £75. per ton, in tin-lined cases; British makers selling for home trade only at these rates, packages free, carriage paid to destination. **Boric Acid,** commercial, crystals, £50; powdered, £52.; B.P., crystals, £56.; powdered, £60.; extra fine, £62. per ton, in free bags, carriage paid to destination; British makers selling at these rates for home trade only; dealers are offering some grades at competitive prices. **Cream of Tartar,** 99/100%, 90/- to 92/- per cwt., in ton lots; at these somewhat easier rates the market is very steady, and some limited business is being done. **Citric Acid,** B.P., crystals, about 1s. 6¼d. to 1s. 7d. per lb., less 5 %; the tone here remains weak and the demand for supplies offering is still poor. **Epsom Salts,** commercial quality, about £5. per ton, in bags; business remains very flat, with prices unchanged. **Formaldehyde,** 40% volume, about £96. per ton; with no business being done the price quoted is nominal. **Glauber's Salt,** commercial quality, £3. 15s. to £4. per ton, in bags; there is seldom any inquiry for this article, and dealers' prices steady. **Lead Acetate,** brown, about £41. to £41. 10s.; white, about £42. per ton; dealers prices are steady at last week's cheaper rates; demand remains slow. **Litharge,** pure flake, British, about £37. per ton; dealers offering imported material at about £36. per ton on a quiet market. **Lithopone,** 30% Continental red seal, £22. to £22. 10s. per ton; at these unchanged rates the market is steady, although business has been slower. **Ammonium Chloride,** grey galvanising, £30. 10s. to £31. per ton; dealers holding imported stocks are asking these unchanged rates, with little doing. **Nickel Sulphate,** home trade, single and double salts, £38. per ton., f.o.b.; British makers quoting at about these figures. **Oxalic Acid,** about 6d. per lb.; the market remains flat, with prices unaltered. **Carbonate of Potash,** 90/92%, about £27. 10s.; 96/98%, about £31. per ton; dealers are asking slightly cheaper rates this week, but business remains poor. **Chlorate of Potash,** crystals and granulated, about 3d. per lb.; there is practically nothing doing in this product. **Caustic Potash, 88/92%,** £32. to £33. per ton, in drums; spot material is available but little is being taken up. **Permanganate of Potash,** commercial quality, about 9¼d. to 9½d. per lb.; at about these prices the market seems fairly steady, but business has been slower of late. **Prussiate of Potash,** yellow, about 1s. 2d. per lb.; stocks on spot are being offered at these prices; some small business is being done. **Sulphate of Potash,** 96%, £11. 10s. per ton, ex ship; the market shows no change on the week. **Mercury,** about £10 5s. to £10 10s. per bottle of 75/76lbs.; a further slight fall in spot values is recorded, with the market dull. **Red Lead,** imported, about £36. per ton.; dealers are finding business quiet, but their prices are unchanged. **Salammoniac,** dog-tooth crystals, £48. 10s. to £49.; medium, £43. to £43. 10s.; fine white

crystals, £26. to £27. per ton; spot material is available, but the demand is still small. **Saltcake,** ground and unground, home trade, about £4. 10s. per ton; export, about £5 5s. per ton, f.o.b.; inquiry has fallen off lately. **Acetate of Soda,** about £25. per ton; dealers offering for forward delivery at about this price. **Soda Ash,** 58% light alkali, £7. 12s. 6d. per ton, in bags, carriage paid to destination; British makers selling at about this rate for home trade only; prices for export vary as to destination. **Soda Crystals,** £5. 5s. per ton, in bags, carriage paid in the U.K.; British makers' prices for home trade only remain at this level; dealers are offering at competitive rates. **Caustic Soda,** 70/72%, £18. 10s.; 76/77%, £20. 10s. per ton, in drums, ex wharf, shipping port; dealers continue to quote at these prices, with business small; British makers' prices for home trade only are unaltered, from £19. to £21. 10s. per ton, in drums; their prices for export vary as to destination. **Bicarbonate of Soda,** £10. 10s. per ton, in bags; British makers selling at this price for home trade only; dealers offering at competitive rates. **Bichromate of Soda,** home trade, 4½d. per lb.; export, about 5d. per lb.; British makers' prices are given. **Chlorate of Soda,** crystals and granulated, about 2⅞d. per lb.; dealers are doing next to nothing in this product. **Cyanide of Soda,** 98/100%; export, about 8¾d. to 9d. per lb.; home trade, about 10½d. per lb.; British makers' prices are unchanged. **Nitrate of Soda,** 96%, £13. 7s. 6d. per ton, f.o.r., Liverpool; at this unchanged price the market keeps steady. **Nitrite of Soda,** 100%, £26. 10s. per ton; there is no change on the week. **Prussiate of Soda,** about 6½d. per lb.; there is no further fall in the price of this article to record; market now steady. **Hyposulphite of Soda,** pea crystals, about £14. 10s. per ton, for pea crystals on the spot, in 1cwt. kegs; commercial quality, £10. per ton, in casks; dealers are offering at about these rates. **Sodium Sulphide,** 60/62%, solid, £14.; ditto, broken, about £15. per ton; importers are offering here at these prices, but business remains very poor; 60/65%, concentrated, £15. per ton; this market is dull and prices are varying; Continental offers are cheap. **Tin Crystals,** 1s. 4d. per lb.; no change to record. **White Lead,** imported, about £43. per ton; dealers are selling small lots at about this rate. **Zinc Oxide,** B.P., about £51.; white seal, about £43.; 99.5%, about £37. 10s. per ton, f.o.r., makers' works; British makers' prices are a shade firmer this week.

Pharmaceutical Chemicals.—After the continued, but slight reductions recorded in this market during the past few weeks, there is very little change to comment upon. Business, if possible, has been even quieter this week, but the holidays probably account for this. **Acetanilid,** crystals and powder, about 1s. 5d. per lb.; this product has been slow in demand, and prices are rather unsteady. **Acetyl-Salicylic Acid,** B.P., 3s. to 3s. 1d. per lb.; spot parcels are steady at these prices, with business quiet. **Benzoic Acid,** B.P., about 2s. 3d. per lb.; there is no change here; no business about. **Diethylbarbituric Acid,** B.P. (barbitone), about 20s. to 21s. per lb.; slightly easier rates are being quoted, with little business about. **Salicylic Acid,** B.P., about 2s. 2d. to 2s. 3d. per lb.; at these rates the spot position is unchanged and keeps steady. **Tannic Acid,** leviss, about 3s. 3d. per lb.; business is on the smallest scale; quoted prices unchanged. **Amidopyrin,** about 14s. to 14s. 6d. per lb.; although the demand is very small, prices are fully maintained. **Ammonium Bromide,** 7d. to 7½d. per lb.; the weak state of the market commented upon during the last few weeks is as marked as ever. **Benzonaphthol,** about 5s. per lb.; nominal; no business on the market. **Benzaldehyde 03,** about 3s. per lb.; this is a steady but quiet market. **Betanaphthol,** resublimed, about 1s. 10d. per lb.; a few inquiries have been dealt with, but not much actual business done. **Calcium Lactate,** about 1s. 9d. per lb.; this product seems steadier after last week's big drop in price. **Chloral Hydrate,** duty paid, about 4s. per lb.; the market keeps steadily up to this figure, and some little business has been done. **Creosote Carbonate,** about 8s. 6d. per lb.; the quoted rate stands as this old figure, with little doing. **Guaiacol Carbonate,** about 8s. 3d. per lb.; nominal, no life in the market. **Hexamine,** about 3s. 10d. per lb.; the spot position seems fairly firm at this recently lowered price, but business has been slow. **Hydroquinone,** about 3s. 6d. per lb.; business continues fairly satisfactory, and prices are maintained. **Methyl Salicylate,** 2s. 5d. to 2s. 6d. per lb.; this market has a steady tone, and some little business has been done. **Methyl Sulphonal,** about 15s. per lb.; hardly any inquiry being received, and quoted rates are unaltered. **Paraformaldehyde,** 3s. 9d. to 4s. per lb.; after the weakening reported last week matters are steadier here. **Paraldehyde,** about 1s. 5d. per lb.; although this price is still quoted, business would generally be at slightly easier rates. **Phenacetin,** about 6s. per lb.; some big lots are offering at slightly under this figure, on spot, with demand quiet. **Phenazone,** about 7s. 6d. per lb.; the spot position is firmer here in most quarters. **Phenolphthalein,** 6s. 6d. to 6s. 9d. per lb.; these high prices continue to be quoted, and the market seems steady. **Piperazine,** about 4s. 6d. per oz., in kilog. lots; no inquiry on the market. **Potassium Bromide,** crystals and granular, 6½d. to 7d. per lb.; the market shows little life, stocks offering freely, and prices are being cut to secure business. **Potassium Permanganate,** B.P., 10d. to 10¼d. per lb.; a steady tone governs the market, which has seen some limited business. **Potassium Sulphoguaiacolate,** about 5s. 6d. per lb.; dealers continue to quote at this level, with no interest shown. **Salol,** 2s. 8d. to 2s. 9d. per lb.; holders of spot stocks continue to quote at these prices, with little doing. **Sodium Benzoate,** about 2s. 6d. per lb.; nominal; the market remains idle. **Sodium Bromide,** crystals and granular, 7d. to 7½d. per lb.; the position on spot is still weak, with business slow. **Sodium Diethylbarbiturate,** about 19s. per lb.; this is about the best price quoted for spot material. **Sodium Salicylate,** powder, about 2s. 5d. per lb.; crystals, about 2s. 9d. per lb.; the spot rates quoted are firmer this week; importations would be much dearer. **Sulphonal,** about 14s. 6d. per lb.; nominal; the market remains idle. **Terpin Hydrate,** about 1s. 9d. per lb.; business is quiet, but prices are steady. **Thymol,** about 15s. per lb.; quoted unchanged on spot.

Coal-tar Products, Intermediates, etc.—Over the holidays things in this market have been very flat indeed; owing to the lack of inquiry quotations have been maintained at about level rates on the week. **Aniline Oil,** about 9d. to 9¼d. per lb., drums free; a steady tone is maintained, with the market quiet. **Aniline Salt,** 9½d. to 10d. per lb., casks free; business remains quiet, with prices quoted unchanged. **Betanaphthol,** 1s. 1d. to 1s. 2d. per lb.; this market has been practically inactive of late. **Benzol,** 1s. 4d. per gallon, f.o.r., makers' works, in buyers' packages; no further decline in quoted rates is likely in this product for some time. **Xylol,** pure, about 2s. 3d.; commercial, about 1s. 6d. per gallon, drums extra; this market is dull and as quoted rather weak. **Naphtha,** about 1s. 5d. per gallon; the demand remains poor, and prices as quoted do not seem firm. **Solvent Naphtha,** 90/160, about 1s. 5d. per gallon, drums extra; dealers' prices show no change; business flat. **Heavy Solvent Naphtha,** 90/190, 1s. 4d. per gallon, drums extra; the market is unaltered on the week, with very little doing. **Special Oil,** for Diesels and motors, 10d. per gallon, barrels free; the market quotation is unchanged, with business small. **Burning Oil,** crude, No. 3 8½d., No. 2 8d. per gallon, barrels free; prices quoted are at these unchanged levels, with the demand poor. **Creosote Oil,** 10d. per gallon, naked, f.o.b.; inquiry for export remains small, but prices are very steady. **Carbolic Acid,** crystals, about 1s. 2d. per lb., f.o.b.; the better tone reported last week continues in this market. **Naphthalene,** £20 per ton; although business is so poor prices appear fairly steady; crude, £7. to £13.; crystals, £21.; powder, about £17.; balls, £28.; candles, £34.; tablets, £34. per ton, packages free. **Disinfectants,** 3s. 9d. per gallon, barrels free; the market is steady but quiet. **Pyridine,** 19s. to 20s. per gallon; nominal; inquiry is good, but there appears to be no stocks to offer on spot, and future imports can only be made at high rates. **Hexamethylene,** 4s. to 4s. 3d. per gallon; these prices are fully maintained. **Pure Methyl Alcohol,** £100. per ton, ex wharf, London; some business continues at about this level. **Pitch,** about 135s. per ton, in London, spot; the tone of the market is now very steady. **Sulphate of Ammonia,** 25¾% neutral, £14. 5s. per ton, delivery over August; September delivery, £14. 10s. per ton.

ITALIAN CHEMICAL MARKET.

Genoa, July 31.

July was an unfavourable month for the Italian chemical market. The continued instability and the violent fluctuations of the foreign exchange rendered importation very difficult. The demand for sulphate of copper was very slight, in spite of the prevalence of disease among the vines, due to the heavy rains. Sulphate of ammonia experi-

enced a considerable reduction in price as a consequence of offers of the German war-reparation product, assisted by a weak demand. Quotations during the month were as follows, prices being per 100kilogs. at Milan, unless otherwise stated: **Caustic Soda,** 70—72%, Italian 185 lire, American 76—78% 210 lire, English 190 lire, French 190 lire. **Carbonate of Soda,** 98—100%, Italian 80 lire, English 85 lire (Genoa), American 85 lire (Genoa); demand stronger than supply. **Soda Crystals,** 50 lire; demand was very good. **Alum,** crystals, 85 lire; in good demand. **Bicarbonate of Soda,** powder, kegs, rose from 159 to 162 lire (Genoa). **Bichromate of Soda,** 445 lire (Genoa). **Potash,** crystals, 590 lire. **Borax Crystals,** 99%, in kegs, 425 lire; in fair call. **Carbonate of Ammonia,** lump 430 lire, powder 370 lire; still in good demand. **Carbonate of Magnesia,** pure, 430 lire; demand fair. **Chlorate of Potash,** crystals in strong request at 310 lire, powder 310 lire (Genoa). **Acetone,** pure, 98—99%, 1,250 lire. **Glacial Acetic Acid,** 99%, lower at 1,200 lire. **Boric Acid,** crystals, 800 lire. **Lactic Acid,** 80%, in fair demand at 600 lire. **Bisulphite of Soda,** crystals, 350 lire. **Formaldehyde,** 40%, in better call at 880 lire. **Phosphate of Soda,** 160 lire. **Hyposulphite of Soda,** crystals 120 lire. **Metabisulphite of Potash,** 400 lire. **Nitrite of Soda,** 96—98%, quiet, and lower at 290 lire. **Permanganate of Potash,** crystals, in better request, at 800 lire. **Sulphate of Alumina,** crystals, 18%, 100 lire. **Sulphate of Zinc,** quiet at 180 lire. **Citric Acid,** crystals, in fair request at 1,900 lire. **Sulphate of Iron,** slow, at 50 lire. **Hydrofluoric Acid,** 50%, in little call at 600 lire. **Oxalic Acid,** crystals, moderate trade, at 660 lire. **Tartaric Acid,** crystals, steady at 1,350 lire. **Chloride of Ammonia,** lump, 98—100%, lower at 600 lire (Milan); powder, 95—96%, in good demand at 325 lire (Genoa). **Chloride of Calcium,** 75—80%, stronger, at 70 lire. **Bleaching Powder** in fair request; French, 110—115%, 90 lire; electrolytic, 100 lire. **Cream of Tartar,** 98—99%, powder, steady at 930 lire. **Yellow Prussiate of Potash,** crystals, dull at 2,000 lire; **Soda,** crystals, 1,400 lire. **Silicate of Soda,** Italian, 38—45%, 65 lire, crystals 85 lire; English, 140° Tw., 100 lire. **Sulphate of Soda,** crystals 43 lire, powder, better at 70 lire. **Sulphate of Magnesia,** crystals, 50 lire. **Chloride of Magnesia,** solid, lower at 75 lire, with little business. **Hydrochloric Acid,** 20—21° Bé., 25 lire. **Sulphuric Acid,** 50° Bé. 20 lire, 66° Bé. 45 lire. **Nitric Acid,** 36° Bé. 150 lire, 42° Bé. 185 lire. **Benzaldehyde,** 3,500 lire. **Tannic Acid,** 80%, 2,000 lire. **Aluminium Acetate,** quiet at 160 lire. **Lead Acetate,** yellow 560 lire, white 570 lire. **Beta Naphthol,** 2,800 lire; in fair demand. **Barium Peroxide,** 1,000 lire. **Sodium Peroxide** in brisker demand, at 1,800 lire. **Red Prussiate of Potash,** not much doing, at 3,150 lire. **Caustic Potash,** 88-92%, 380 lire. **Tartar Emetic,** powder, 1,200 lire. **Mineral Superphosphate,** 28 lire. **Bone Superphosphate,** in strong demand, at 53 lire. **Basic Slag,** 16—18%, little business at 37 lire. **Nitrate of Soda,** 15—16%, 142 lire. **Nitrate of Ammonia,** 15—16%, lower at 120 lire. **Nitrate of Lime,** 12—13%, dull at 110 lire. **Sulphate of Ammonia,** 20—21%, quotations reduced to 163 lire, with small demand. **Sulphate of Copper,** 98—99%, Italian 225 lire, foreign 226 lire. **Chloride of Potash** rose from 72 to 78 lire. **Sulphate of Potash** in good call at 100 lire. **Calcium Cyanamide,** 15—16%, quieter at 105 lire. **Sulphur,** refined, in blocks, 53 lire (Catania, Sicily), 70 lire (Milan). **Sulphur,** sublimed, 70 lire (Catania, Sicily), 77 lire (Genoa). **Green Olive Oil,** 360 lire. **Pure Olive Oil,** Riviera 825 lire, Pari 650 lire, Molfetta 625 lire, Bitonto 650 lire, Calabria 625 lire, refined 750 lire. **Raw Tartar,** quotation reduced to 310 lire.

LONDON METAL MARKET. Wednesday.

Copper: Standard brands, £64. 12s. 6d. to £64. 15s., cash; £65. 7s. 6d. to £65. 10s., three months; electrolytic, £71. to £71. 10s. **Tin**: Standard, £184. 10s. to £184. 12s. 6d. cash; £185. to £185. 5s., three months; Straits, £188.; English, £185. **Lead,** soft foreign, £24. 2s. 6d., prompt; English, £25. 5s.; chemical sheet, 33s. per cwt. for 2-ton lots, delivered. **Spelter,** prompt, £31. 12s. 6d.; hard £25. 5s. **Antimony,** English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35. **Aluminium,** 98—99%, £115. to £120.; foreign, £110, c.i.f. **Nickel,** £130., delivered; £125. to £130. for export, f.o.b. **Mercury,** £10. **Bismuth,** 10s. **Platinum,** 500s. per oz. **Wolfram,** spot, 12s. 6d. to 12s. 9d. per unit, c.i.f., United Kingdom or Continent. **Zinc Dust,** quotations are as follows: Highest grade English, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET Wednesday.

There are no signs of improvement in the demand for heavy chemicals, and prices generally have still a downward tendency, with buyers only covering for spot or near requirements. For **Alkali** products the current quotations are unchanged. **Chlorates** and **Bichromates** are easy at recent rates, with only a small inquiry. **Bleaching Powder,** softwoods, dull, at £11. 5s. on rails. **Roasted Saltcake,** firm, at £4. 10s. per ton, carriage paid. For **Sulphate of Copper** the demand is quiet, and price remains nominal, at £26., f.o.b. American **Sulphur,** steady, at £5. 5s., on rails. There is little or no business doing in **Phosphate** and **Hyposulphite of Soda,** and prices are easy; **Nitrite,** 96%, well maintained at £26. 10s., ex store. Concentrated **Sodium Sulphide,** weak, at £15. White powdered **Arsenic** is fairly steady at £70. on rails, Cornish works. **Yellow Prussiates** have again declined in value; **Potash** to 1s. 2d. and **Soda** 6¼d. per lb. **Carbonate** and **Caustic Potash** are short on the spot and quotations firm. Grey and brown **Acetate of Lime** continue scarce and the high prices are well maintained. **Acetic Acid** unchanged. **Acetate of Soda** is again easier, at £23. 10s., c.i.f. **Lead Salts** are dull; white **Acetate** at £41., brown £43.; and **Nitrate,** £42., delivered. **Acetone,** higher, at £125. per ton. **Green Copperas** is in fairly steady demand. **Barium Chloride,** unaltered, at £15. per ton. **Oxalic Acid,** difficult to move, at 6d. per lb. **Permanganate of Potash,** firm, at 9¾d. to 10d. per lb.

SWANSEA MARKET REPORT Wednesday.

Tinplate prices unchanged on basis of £1. 3s. 1½d. per standard box, f.o.b. **Galvanised Sheets,** in better demand, at £17. 15s. per ton. **Copper,** easier, at £64. 17s. 6d., prompt, and £65. 12s. 6d. per ton, three months. **Tin,** irregular, at £181. 17s. 6d., prompt, and £182. 17s. 6d., three months. **Lead,** steady, at £24. 2s. 6d. per ton, prompt, and £23. 17s. 6d., forward. **Spelter,** firm, at £30. 17s. 6d. per ton, prompt, and £30. 12s. 6d., three months. **Zinc Sheets,** in fair demand, at £38. 17s. 6d. per ton. **Linseed Oil,** quiet, at £2. 3s. 3d. per cwt., in barrels. **Cottonseed Oil,** in good demand; common edible, £2. 4s. 6d., and deodorised, £2. 7s. 6d. per cwt. **Rape Oil,** slow; refined, prompt, £2. 5s. 3d., net, in barrels. **Cod Oil,** scarce and nominal. **Palm Oil,** quietly steady; Lagos, prompt, £32. 2s. 6d.; softs, £31. 10s. 6d.; mediums, £32. 2s. 6d.; and hards, £32. 7s. 6d. per ton. **Turpentine,** quiet, at £3. 14s. 6d. per cwt. **Oxalic Acid,** dull, at 6¼d. per lb. **Sulphate of Copper,** quiet, at £26. 12s. 6d. per ton, less 5%, in casks, f.o.b. **Arsenic,** in poor demand, at £72. 2s. 6d. per ton for white powdered. **Nitrate of Soda,** in moderate demand, at £13. 12s. 6d. per ton, f.o.r. **Pitch,** dull, at £6. 12s. 6d. per ton, at docks. **Copperas,** slow, at £2. 2s. 6d. per ton. **Sulphate of Ammonia,** in better inquiry. **Sulphuric Acid, in steady call, at** £3. 12s. 6d. up to £6. 12s. 6d. per ton. **Coals,** owing to the holiday season, were rather dull market; best Admiralty smokeless, £1. 10s. 9d. to £1. 12s.; Monmouthshire black vein, £1. 8s. 10d. to £1. 9s.; small, £1. 2s. 6d. per ton. **Anthracite** in better demand, best large £2. 11s. 3d. to £2. 12s., best nuts £3. 1s. 3d. per ton f.o.b. **Cokes** continue in strong demand, with best qualities, for export, up to £3. 2s. 6d. per ton, f.o.b.; foundry £2., and furnace £1. 10s. per ton on rails at ovens. **Patent Fuel,** £1. 13s. 9d. to £1 10s. per ton.

LIVERPOOL CHEMICAL MARKET. Wednesday.

Business in the heavier chemicals has been quiet, the August holiday period having tended for the time to restrict the moderate inquiry for such chemicals that existed through the previous two weeks. The continued labour strain in some industries, and the uncertainties as to production arising therefrom, have also had a restricting influence, and have tended to lengthen the August holiday period. Shipments on foreign account have gone on steadily and have been on a fair scale. **Bleaching Powder** has been quieter, and is £10. to £11. per ton for use in the United Kingdom,

and £11. per ton for export. **Calcium Chloride** has been in fair request, and is £5. 17s. 6d. per ton. **Caustic Soda** has been in moderate demand for use in the U.K., and has had a very fair shipment for foreign ports; the price is £20. 7s. 6d. to £21. 7s. 6d. per ton for 76%, carriage paid, for home-trade use; and £20. 10s. per ton for export. **Bicarbonate of Soda** has been steadily called for on home-trade account, and has had a moderately active shipment for export; the price is £10. 10s. per ton, carriage paid, for use in the U.K. **Soda Crystals** have been in fair demand, and are £5. 5s. per ton for home-trade uses. **Nitrate of Soda** has been quiet, and is £13. 5s. to £13. 10s. per ton. **Borax** has been inactive; commercial crystals are £27. per ton, and powdered £28.; higher grades are, crystals £31. per ton, and powdered £32. per ton, carriage paid in the U.K. **Saltcake** has been in moderate demand, and is £4. 10s. to £5. per ton for the home trade, and £5. to £6. per ton for export. **Bichromate of Soda** has moved but slowly, and is 4½d. per lb., c.i.f. to usual ports. **Ammonia Alkali** has been in fair request for use in the U.K., and has been shipped rather freely for export. **Hyposulphite of Soda** has been rather more in demand; it is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial, and £15. to £16. per ton, in 1cwt. kegs, for photographic. **Sulphide of Soda** has been but little called for; solid is £16. per ton, and crystals £10. 10s. to £11. per ton. **Chlorate of Soda** has had a slow sale, and is 3d. to 3½d. per lb. **Phosphate of Soda** has been very quiet, and is £15. to £15. 10s. per ton. **Prussiate of Soda** has been but little in demand and the price has eased; it may be given as 7d. per lb. **Yellow Prussiate of Potash** has been in quietly steady request, and is somewhat cheaper; the price is 1s. 2½d. to 1s. 3d. per lb. **Red Prussiate** has been quiet, and is 3s. 6d. to 3s. 9d. per lb. **Carbonate of Potash** has been but little in demand, and is £25. to £32. per ton, according to quality. **Nitrate of Potash** has had a moderate sale, and is £33. to £35. per ton. for refined. **Chlorate of Potash** continues very quiet, and is 4d. per lb. **Caustic Potash** has had a limited inquiry, and is £32. to £33. per ton. **Permanganate of Potash** has been quieter, and is 9¾d. to 10d. per lb. **Bichromate of Potash** has moved slowly, and is 5¾d. per lb. c.i.f. to usual ports. **Salammoniac** has been but little demand; first quality is £63. per ton, second £60., and third £57. **Sulphate of Ammonia** has been reduced; neutral is £14. 5s. per ton, and ordinary £13. 2s. per ton, for August. **Carbonate of Ammonia** has had a moderate sale, and is 4d. per lb. **Muriate of Ammonia** has been but little called for, and is £32. to £33. per ton. **Magnesia** has been in fair demand; **Carbonate** is £2. 5s. per cwt., and **Sulphate** £5. to £6. per ton. **Alum** has been quieter, and is £12. per ton for export. **Sulphate of Alumina** has had a very limited inquiry, and is £8. to £11. per ton, according to quality. **Sulphur** has been quiet; flowers are £10. per ton, roll is £8. 10s. per ton, rock £8 to £8. 10s. per ton, and American £5. to £5. 10s. per ton. **Tartaric Acid** has had a steady sale, and is 1s. 2½d. to 1s. 3d. per lb. **Cream of Tartar** has been in very fair demand, and is £4. 12s. to £4. 15s. per cwt. **Boric Acid** has been in quietly steady demand; commercial crystals are £52. per ton, and powdered is £58., £2 per ton more being charged if in casks. **Citric Acid** has been quieter, and is cheaper; the price may be given as 1s. 7d. to 1s. 9d. per lb. **Oxalic Acid** has had a slow sale, and is 6d. to 6¼d. per lb. **White Acetate of Lead** has been but little called for, and is £42. to £43. per ton. **Sulphate of Copper** has again been quiet in the export branch, and in the home branch of the trade; the price is £26. to £26. 5s. per ton, less 5%, in casks, f.o.b. at Liverpool. **Arsenic** has been very quiet; white powdered is £72. per ton.

WEST OF SCOTLAND CHEMICALS. Wednesday.

A little more activity has been noticeable in the Glasgow market during the week, and business, though still of small dimensions, is considered as having a more hopeful tone. The usual day-to-day demand for chemicals on home account is maintained, but inquiries for export are still of a limited character. Prices generally are steady, with some improvement to be noted in lead acetates. Quotations, at Glasgow, are as follows:—**Alum,** quiet, and in small demand; prices steady, at £12. 5s. for lump, and ground £12 per ton. **Arsenic** continues in short request, and supplies are still very scarce; it is quoted on spot at £77. net. **Barium Chloride** remains very quiet, despite the recent reduction to £15. per ton. **Bleaching Powder** does not show much movement, and the quotation still stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax,** granulated, is on offer at £26. 10s. per ton net, in 2cwt. bags. **Calcium Chloride,** 70—75%, solid, £5. 12s. 6d. per ton. **Citric Acid** is a declining market, with the price reduced to 1s. 7¼d. per lb., less 5%. **Copper Sulphate** is but little in request at last week's figure of £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar,** easier, with better inquiry, at £4. 8s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in fair request; brown steady at £41. per ton, net, and white better at £41. 10s. per ton, net. The market for **Magnesium Chloride** is slow, with quiet business at £3. for spot. **Oxalic Acid** at 6¼d. per lb. **Paraffin Wax** experiences a fair export trade at 2¾d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull at the rather easier figure at 1s. 3¼d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1. 11s. per cwt., but business is nominal. **Sodium Bichromate** remains steady, with business on the basis of 4½d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2cwt. bags; and £11. 10s. in 1cwt. kegs. **Tartar Emetic,** 43—44%, in fair request at 1s. 1½d. **Tartaric Acid** still shows a quieter tendency at 1s. 2¾d. per lb., less 5%, Glasgow.

IMPORTS OF CHEMICAL PRODUCTS

At the Principal Ports of the United Kingdom.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers)	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."

Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

A NOVEL NITROGEN-FIXATION PROCESS.

IT is now more than eighty years ago since the suggestion was first made by T. Sterry Hunt that it might be possible to hydrolyse nitrogen gas with the direct formation of ammonium nitrite. The theory underlying this suggestion is that since the molecule of nitrogen consists of two atoms, and since the great stability of molecular nitrogen can only be explained satisfactorily by the hypothesis that the constituent atoms possess opposite electrical charges; hydrolytic decomposition of the nitrogen under suitable conditions should give rise to the formation of the electro-positive ammonium ion from one of the nitrogen atoms, and the electro-negative ion of nitrous acid from the other. Similar views have since been advanced from time to time, but the experimental difficulties in the way of proving the theory have been so great, and those results that have been obtained are so conflicting, that the reaction has become almost discredited. It would appear, however, from recent work carried out by H. George Falk, of New York, and Professor R. H. McKee, of Columbia University (*Chemical and Metallurgical Engineering*, August 6, 1923), that the reaction does take place, and to quite a definite extent; and that it may possibly form the basis of a new and simple method of nitrogen fixation. In the first experiments in which nitrogen at 300 pounds pressure was maintained in contact with water at the ordinary temperature, approximately six parts of nitrogen per million were found to have been hydrolysed, and the products formed were ammonium nitrite and ammonium nitrate, the latter compound possibly resultant upon the presence of accidental traces of oxygen. In glass or silica vessels the reaction did not take place until a clean piece of iron was present. Increasing the pressure of the nitrogen to 1,800 pounds per square inch gave an increased yield, which was still further augmented by employing an alcohol-acetone-water mixture instead of water alone. As the American chemists point out, it is very much easier to work at ordinary or low temperatures with water and nitrogen, than it is to work at red heat with gases such as the nitrogen-hydrogen mixture at present used; and, although the results so far obtained are negligible, from the economic standpoint, it is far from impossible that by the discovery of a suitable catalyst, and the use of the

very high pressures, the process might emerge into the realm of practical politics.

OUR JAPANESE ALKALI MARKET.

In these days, when the loss of several of our overseas markets for chemicals, and the serious shrinkage in the shipments to many others are so frequently lamented, it is a pleasant relief to be able to record a case in which the British manufacturer has regained completely his pre-war position. Such a case is the Japanese market for soda ash and for caustic soda. According to reports from our Japanese correspondent at Osaka, after a period of fierce competition and ruthless price-cutting, British alkali manufacturers have now recovered their dominant position. Of the three Japanese soda-ash producers, two ceased operations some time ago, and the third, the Asahi Glass Company, has just completed a contract for ten thousand tons of British soda ash, and has closed down its own alkali plant. It appears also that Magadi soda importers have found the competition of the British-produced ash too keen, and have ceased to import. With regard to caustic soda, the price drop of 25 sen per 100 pounds made by Brunner, Mond, and Company on the 11th of last month has already produced satisfactory results, American producers obviously finding it impracticable further to reduce quotations below their last figure of 9.50 yen per 100 pounds for spot delivery. The Japanese product itself has for some time been offered considerably below cost, and it is difficult to see how the present quotation can be maintained, let alone lowered much further.

TRADE RETURNS.

The Board of Trade returns for July show that the month's import figures are the lowest since February, 1922, while there is a decrease of £12½ million on the June total. Exports have declined by nearly £3½ million on the June figures, and by £12 million on those of May. It is impossible to say how far these movements may represent trade which has been totally lost as a result of the dockers' strike, and how far mere postponement has occurred. The stoppage at the Port of London continued throughout the month, while Hull, Manchester, Liverpool, and other ports had their business stopped in the first part of the period. The opening-up of these ports allowed a considerable transference of traffic to them from London, otherwise the trade figures must have been much worse. There is a limit, however, to this kind of diversion of trade, and it appears to be increasingly imperative that immediate action in connection with the strike should be taken. It will be realised, therefore, that the figures for July alone indicate quite a different position when compared with those for the seven months since the beginning of the year. Conclusions deduced from an examination of the larger figures are much more hopeful, the total imports at £616,000,000. exceeding the figure for the seven months in 1922 by £47,000,000., while British exports were £30,000,000. better at £442,000,000. Although these figures point to a better general trade position, it is a little disturbing to find that the main increase in our exports during the period is to be attributed to raw materials, chiefly coal, exports of manufactured articles being only just over one per cent. higher than last year. So far as the general direction of trade is concerned, it is interesting to note that in the period January to June, 1923, British exports to the United States have considerably increased, as compared with 1922, while the value of our imports from that country has fallen by a small percentage.

NATIONAL CERTIFICATES IN CHEMISTRY.

The arrangements and conditions for the award of national certificates in chemistry to students in technical schools and colleges in England and Wales, have just been issued as a white paper by the Board of Education (H.M. Stationery Office, 2d. net). It will be remembered that under this scheme the Institute of Chemistry was invited, and has undertaken to work in co-operation with the Board in approving submitted schemes of training, in conducting the final examinations, and in awarding the certificates to successful candidates. Four types of certificates are to be issued, senior and advanced part-time course certificates intended mainly for students at evening classes, and full-time course certificates in chemistry and in applied chemistry intended for students who have attended a secondary school up to the age of 16. Full-time course certificates in chemistry will necessitate attendance at a course extending over at least three years, and an additional minimum period of study of one year after this course must be spent by the candidate for the certificate in applied chemistry. The conditions of award of the certificates are not too onerous, and it should be easily within the capacity of the average student to qualify. What the ultimate value of these certificates will be, only experience can decide. As stepping stones to higher examinations they will undoubtedly be of advantage, but their economic value to those who do not intend to pursue further their studies of chemistry is, to say the least, problematical.

THE FORMALDEHYDE DECISION.

The referee, appointed under Part I. of the Safeguarding of Industries Act, has given his decision in the formaldehyde appeal case. The complaint of the Chemical Merchants' and Users' National Vigilance Committee, that formaldehyde has been improperly included in the list of articles prepared by the Board of Trade as dutiable under Part I of the Act, has been found to be valid, and as from Monday, the 20th inst., the substance will be withdrawn from the list. It is not known yet which of the points raised by the complainants carried most weight with the referee. It is true that their contentions, firstly that formaldehyde production from natural methyl alcohol is not a true synthesis, and secondly that the material is not a generally acknowledged analytical reagent, possess a certain amount of validity, but we cannot help thinking that the decision is somewhat against the spirit in which the Act was framed.

THE TECHNOLOGY OF SOLDERING MATERIALS.

A COMPREHENSIVE REVIEW OF MODERN PROGRESS.

By "Metallurgicus."

THE fusible alloys used for soldering purposes are usually classified as "hard" and "soft" solders, according to their melting point. Hard solders comprise the various brazing alloys, silver and gold solders, while the soft solders are predominantly lead-tin alloys, melting as a rule below 300° C. Fusibility, temperature range of solidification, hardness and chemical composition, are some of the factors which determine the utility of a solder, the constitution controlling the tendency to form solid solutions with the metals to be united. Thus microphotographic examination shows that brazing alloys actually diffuse into and alloy with the brass of the joint, a similar effect resulting when ordinary plumbers' solder is applied to brass (Sterner-Rainer, *Zeit für Metallkunde*, 1921). For ease of application, soldering alloys should be more fusible than the metals to be joined, and for a union of maximum strength, they should be of the same hardness and malleability as the metal. High fusibility is a factor of particular importance in aeroplane work, where the effect of heat on mechanical properties has to be considered.

The Manufacture of Soldering Alloys.

The preparation of the alloys under consideration is carried out so as to obtain uniformity of composition and to minimise losses by volatilisation and oxidation. For this purpose the least fusible constituent is completely melted first and the other metals then added, stirring being effected by means of a piece of greenwood, so as to reduce any oxide formed. Brazing alloys are fused under a layer of powdered borax or charcoal and then granulated or cast in ridged iron moulds, so that the resulting cake can easily be broken up. The pieces are then heated to a red heat, ground in a mortar and the powder sifted to size. Another method is to pour the melt in a thin stream through a broom of twigs into water, which is kept in motion; or, again, the metal is allowed to flow in a thin stream through a water-jet on to a rotating disc, from which the particles are flung into water. Granulation can also be effected by means of a high-pressure steam jet, after which the granules are dried by shaking with sawdust in a sieve. Soft solders are generally melted under tallow and then cast into sticks or run off into strips, or they can be granulated by shaking in a closed iron vessel lined with a thin layer of plaster. Gold and silver compositions are usually rolled into sheets and then cut into strips or drawn into wire.

The More-important Soft Solders.

As stated above, soft solders are usually lead-tin alloys, melting below 300° C., and should be free from zinc. Additions of bismuth and cadmium serve to lower the melting point without increasing the strength, while the alloys may be hardened by adding up to 10 per cent. of antimony. The ductility is very low, being still further reduced by antimony, which, together with zinc and aluminium, has a deleterious effect on the adhesive properties of the solder. For soldering zinc, copper may be incorporated with good results, while the addition of phosphor-tin (tin containing a small proportion of phosphorus) is also beneficial.

In the series of lead-tin alloys, the most fusible and most homogeneous solder consists of the eutectic mixture, which solidifies at about 170° C., and contains 37 per cent. of lead. Ordinary plumber's solder, composed of 2 parts of lead and 1 part of tin, with possibly 1 per cent of antimony, begins to solidify at about 60° C. above the eutectic freezing point. This extended range of solidification imparts a pasty consistency to the cooling solder, enabling the material to be shaped to the joint (the plumber's "wiped" joint). For soldering cans a long temperature range of solidification is not essential, ready fusibility and fluidity being the qualities desirable. For this purpose the eutectic alloy would be ideal, but would be too costly, alloys containing 60 per cent. of tin, and even less, sufficing. In soldering pewter ware, the proportion of lead must be cut down for reasons of safety. A tin copper alloy, melting point 257° C., has been patented as being suitable for cast iron, the composition being given as cobalt 2.2 per cent., copper 10 per cent., silver 0.6 per cent., antimony 0.6 per cent., and tin 88.6 per cent. (*Brit. Pat.* 159,797 of 1920). The composition and melting points of some widely used products are as follows:—

—	M. Pt. ° C.	Tin. Per cent.	Lead. Per cent.	Bismuth. Per cent.
Plumber's soft solder	188	50	50	—
Plumber's coarse solder	227	33·3	66·7	—
Tinsmith's fine solder	168	66·7	33·3	—
Tinsmith's ordinary	171	60	40	—
For cans	—	59	37	4
For tinned iron	275	12·5	87·5	—
For pewter	96	25	25	50

Effect of Cadmium in Soft Solders.

With a view to reducing the cost, attempts have been made to introduce cadmium into soft solders in place of tin. A study of lead-cadmium alloys showed that the one containing 8 to 9 per cent. of cadmium had good tensile strength and a solidification range extending from 275° to 248° C. When applied to copper, however, this alloy does not flow very evenly, the addition of a considerable percentage of tin being necessary to overcome this defect. A satisfactory solder results on adding 5 per cent. of zinc (*U.S. Pat.* 1,333,619 of 1920). A lead alloy consisting of 80 per cent. lead, 10 per cent. tin, and 10 per cent. cadmium is claimed to have about the same tensile strength but double the ductility of an ordinary 60 per cent. lead—40 per cent. tin solder. The temperature of complete liquidation is only slightly higher, but the freezing range is much more extensive. Owing to its relatively higher lead content such a solder would be low in price (*U.S. Pat.* 1,301,688 of 1919).

Brazing Alloys and Other Hard Solders.

Hard solders are generally used for very strong joints which are liable to be subjected to high temperatures. The brazing alloys melt at about 1,000° C., which temperature can be lowered by adding cadmium, the presence of tin being undesirable. For brass, copper, iron, and steel, spelter (equal parts of copper and zinc) may be used, the zinc content being increased for pale brasses, while for iron work the copper content is augmented. According to some recent comparative tests, the strongest joint is given by an alloy consisting of 83 per cent. of copper and 17 per cent. zinc (*Tech. Review*, 1921). Recent metallographic study shows that with steel, a constituent intermediate in composition between the alloy and the steel is formed, producing a zone of great strength.

For soldering silver ware, "silver" solders with high silver content are used, and these can also serve as hard solders for brass, copper, iron, and steel. Thus ordinary coil silver is useful for iron, copper, and high-melting-point brass. Arsenic figures as a constituent of some silver solders—*e.g.*, one contains equal parts of silver, arsenic, and brass,—while a soldering composition consisting of silver 55-65 per cent., copper 20-30 per cent., zinc 10-20 per cent., together with arsenic trioxide, is the subject of a recent specification (*U.S. Pat.* 1,375,552 of 1921).

For jewellery, solders consisting largely of gold, together with silver and copper, are used—gold of the same fineness as the article itself being preferably used. Cheaper ornaments are soldered with a composition consisting of brass and gold, but antimony, arsenic, tin, and lead should be absent. Nickel silver (copper-nickel-zinc alloy) can be brazed with an alloy of similar composition in which some of the zinc has been replaced by manganese. The latter is added as cupro-manganese. Nickel silver itself and copper-zinc-manganese alloys find application for iron and steel brazing. In the following table are given some data in connection with some hard solders:—

	Silver. Per cent.	Copper. Per cent.	Zinc. Per cent.	Gold. Per cent.	Other Metals. Per cent.
Silver solder	78	17	5	—	—
" "	75	20	5	—	—
" " for steel	80	15	5	—	—
For bronze, gunmetal, brass	50	33	17	—	—
" " " "	6	47	47	—	—
Brazing alloy for steel	40	29	4·5	—	Cd. 20·5 & Mn 6·0
Gold solder	7	3	—	90	—
" "	—	7	3	90	—

Fluxes for Soldering.

For an efficient union with any solder the metal surfaces much be mechanically and chemically clean. The film of oxide usually present prevents the solder from properly

wetting the metal, and so impairs the adhesion. It has been proposed to operate in an atmosphere of reducing gas in brazing, but for practical purposes fluxes are generally employed. The latter are threefold in function: they decrease the surface tension of the molten solder and so improve its wetting power; they dissolve away any oxide film; and, lastly, they protect the heated metals from further oxidation. Borax and boric acid are the usual brazing fluxes, organic compositions being precluded owing to the high operating temperatures. To obtain a "cooler" medium—that is, to lower the melting point—a mixture is often used, one consisting of five parts of boric acid with two parts of borax being very efficacious. Metal borates are formed, which dissolve in the excess of the flux.

For soft soldering a variety of materials are available, both inorganic and organic. The inorganic fluxes are "killed spirits"—that is, zinc chloride, both fused and in solution, for brass, copper, gunmetal, and tinplate; salammoniac for copper and iron, and hydrochloric acid for zinc and galvanised products. Among organic fluxes are resin for soft alloys, turpentine for pewter and Britannia metal, and palm oil and tallow for light and heavy lead work respectively. The action of the resin is to dissolve the oxides with the formation of resino-resinates, and, unlike zinc chloride and hydrochloric acid, there is no tendency towards subsequent corrosion. Fused zinc chloride ground with salammoniac, and zinc chloride compounded with petroleum jelly, are the chief constituents of some well-known soldering fluxes. Two useful fluxes consist of phosphoric acid dissolved in alcohol and aqueous lactic acid dissolved in glycerol. For lead-cadmium solders a flux of the following composition is recommended: NaCl 11 per cent, KCl 14 per cent, salammoniac 10 per cent, and fused zinc chloride 65 per cent. (*Chem. and Met. Eng.* 1918).

Frequently the solder is ready mixed with the flux in the form of pastes. For instance, granulated soft solder and zinc chloride are made into a paste with beeswax or with celluloid. Such compositions can be applied with a brush, and are especially useful on vertical surfaces. Tubes of soft solder filled with resin can be obtained, while such compositions as $ZnCl_2$ 40 per cent., NH_4Cl 45 per cent., Zn 15 per cent.; and NH_4Cl 1, borax 2, mercury 5, tin 20, and lead 26 parts, are the subjects of recent specifications (*Brit. Pat.* 170,221 of 1920, and *U.S. Pat.* 1,357,297 of 1920).

The Problem of Soldering Aluminium.

The vexed question of a satisfactory solder for aluminium still awaits solution. The metal is electro-positive to all the soldering alloys, so that electrolytic action sets in at the joint, leading to rapid corrosion. Joints exposed to moisture should therefore be protected by painting or varnishing. Another difficulty is the ease with which an oxide film, very difficult to remove completely, forms. Further, aluminium only alloys at a high temperature. Ordinary lead solders cannot be used, as they alloy only with great difficulty. According to a recent investigation of the United States Bureau of Standards (*Circ.* 78, 1919), the most satisfactory solders are zinc-tin alloys with or without aluminium—*e.g.*, zinc 15-50 per cent., tin 85-50 per cent., zinc 8-15 per cent., and aluminium 15-50 per cent., the remainder being tin. There are applied without a flux after tinning the aluminium, the higher the temperature of the latter operation, the better the adhesion. Brittleness results with a too high aluminium content, or when copper or antimony are present. A soldering alloy which is stated not to crack away when an aluminium casting cools down has the following complex percentage composition: Al 85, Cu 6.5, Zn 4.5, Fe 2.0, Si 1.5, and Pb 0.5 (*German Pat.* 340,294, of 1919).

Another method proposed for soldering aluminium is to electroplate the metal with a film of iron, which is then tinned, so that it can be soldered in the usual way. The plating bath consists of equal parts of 4 per cent. ammonium oxalate and 2 per cent. ferric-sulphate solutions, a current density of 0.15 amp. per sq. dm. of cathode being used (*Brit. Pat.* 134,315, of 1918). The table at the head of the next column gives some of the host of compositions recently patented.

Many soldering fluxes for aluminium have also been proposed, the chief being phosphor-tin, cryolite Na_3AlF_6, stearic acid, and various alkali chlorides and fluorides. Thus one composition consists of equal proportions of tin, zinc, lead, and stearic acid, together with a little skunk oil (*U.S. Pat.* 1,321,529, of 1919). Another contains cryolite, and the chlorides of ammonium, lithium, and manganese (*Brit. Pat.* 152,486, of 1919).

In order to overcome the soldering difficulty, autogeneous welding of aluminium has been introduced. Here the molten aluminium itself acts as the solder, but the presence of the almost infusible Al_2O_3 is a difficulty. Various welding fluxes are used, many being sold under such trade names as "autogal" and "zasa." These either protect the metal from oxidation (alkali chlorides) or act as solvents for the oxide (cryolite, sodium, potassium, lithium and aluminium fluorides, alkali bisulphates and pyrophosphates). One such medium consists of KCl 45 per cent., NaCl 30 per cent., KF 7 per cent., LiCl 15 per cent., and 1 to 10 per cent. of alkali pyrosalts (*Brit. Pat.* 170,343, of 1920).

PLATINUM IN THE UNITED STATES.

RESOURCES PROVED TO BE NEGLIGIBLE.

THE main source of the world's supplies of platinum is normally Russia, which once had an output of 300,000oz. per annum, derived from gravel beds. As a result of the war the price of platinum is about three times what it was formerly, and the temptation has apparently been considerable in the United States to boom platinum mining in that country. To this end, all sorts of properties have been pronounced to be capable of producing platinum from ores of various kinds and even shales and sands. As a matter of fact the country, save in very small quantities, is practically as destitute of platinum, as it is of nickel and tin, and the cases in which the United States Bureau of Mines has been able to check claims advanced, have revealed at the most practically unworkable traces of the metal. Platinum was the subject of a good deal of prospecting and assaying on the part of the Bureau during the war, when it was thought that such work might reveal sources of supply which would then have been very valuable. The work, then and since carried out, served for the most part to convince the officials that the platinum resources were, however, very small. At its best the United States have produced less than 1,000oz. a year, and that as ancillary to the working of gold, silver and copper, without which the platinum recovery would have been uneconomical

The Bureau's investigations have led to the examination of a large number of samples, in most of which no platinum whatever was discovered though rich claims had been made and certified. In one case platinum was found in the form of soluble platinum salts and sponge, "neither of which exists in nature," to quote the damaging judgment of the Bureau; another "sample revealed wire and foil therein." As it had been claimed that many of the samples did not lend themselves to ordinary assay methods, and most of the promising claims were made in connection with special methods of analysis or assaying, the Bureau instituted a number of tests of a similar character, but with negative results. The fire assay method is held in all cases by the Bureau to be the most effective and reliable. The relatively small quantities which have been recovered in conjunction with work on other metals have mainly been from well-known lode deposits in Wyoming, Nevada, Colorado and Alaska. In all these cases the platinum is present in very small quantities and is only recovered as a by-product, usually in working copper ore. Black sand deposits have been tested but found to contain nothing workable, but the black sand concentrate from dredges and hydraulising plants has been found to yield recoverable quantities. As the dredges alone handle over 50,000,000 cub. yards of gravel per annum the actual platinum content is infinitesimal and would not be workable alone.—*Engineering.*

INDIA'S HEAVY-CHEMICAL INDUSTRY.

A BRIEF SURVEY OF THE ACTUAL POSITION.

By F. R. Lowe.

THE heavy-chemical industry in India has since the war been a very attractive field for chemists and chemical engineers. During the boom period of 1919 to 1920, many schemes were discussed and more or less attempted, but the rapid decline of the rupee to its pre-war value proved the death-blow to the great majority of these schemes. The directorates of industry in the various presidencies have gathered together staffs and statistics showing the demands and resources of the country, but the net result cannot be said to be very encouraging. This is not the place, however, to go into the whys and wherefores of the relative failure of these directorates.

Sulphuric-acid Manufacture.

The heavy-chemical industry of India may be said to comprise sulphuric acid, aluminium sulphates, sodium sulphide, nitric acid, hydrochloric acid, magnesium sulphate, sodium sulphate, and zinc chloride. Sulphuric acid has been manufactured in India for many years, one of the first large factories being that at Cossipore, near Calcutta, which was later removed to the right bank of the River Hooghly, about fourteen miles from Calcutta, and is still in existence. Other factories are situated at Bombay (2), Ranejunge, Lodna, Loyalad, Bowrah, Bararree, Tatanajar (2), Cawnpore, Calcutta, and Madras. The factories at Ranejunge, Lodna, Loyalad, Bowrah, Banaree, and one at Tatanajar produce solely for sulphate-of-ammonia manufacturing purposes, with small quantities of concentrated acid for benzol refining at the coke-ovens. One at Jamshedpur is manufacturing the acid for galvanising purposes only.

The output of the various plants given above is notoriously higher than the requirements for ammonia absorption necessitate. Two at least of the factories are reputed to be capable of producing 10,000 tons of chamber acid per annum, and the remainder down to 1,200 tons per annum. As there are no large deposits of pyrites or sulphur available in India, sulphur is in all cases burnt, mostly imported from America, No practical difficulty exists in working the chambers with or without Glover and Gay-Lussac towers, five plants at least not having these adjuncts.

The plants at the coke-ovens do not yet cater for buyers of strong acid, but there is no doubt that in the near future they will do so. They have the initial advantage in that fuel, coal or coke, has not to pay the heavy freight which is such a burden on plants further from the coalfields. The demand for acid of 1.84 gravity probably reaches 700 tons per annum, and, generally speaking, the quality required is much higher than that in England. This appears to have arisen from the fact that in the early days acid was made from the best sulphur in small chambers without towers, and thus no exterior impurities were in the acid, which is often water-white.

There are optimists who think that in the next few years the demand for superphosphates will influence the output of sulphuric acid. Whether this is or is not the case, there is undoubtedly an increasing demand due to the manufacture of soda and other aerated waters.

Transportation of the commercial acid is generally effected by means of 2½gal. jars and 5gal. carboys, although in one case a small tank is occasionally used, and in another steel drums of 40gals. capacity. With regard to these steel drums, they are used to transport 1.84 acid, and owing to the heat, action on the steel and cast-iron bungs and seatings takes place. The greatest corrosion was on the bungs, but this source of trouble has been eliminated by coating the bungs and seatings with paraffin wax. Painting the drums white has also helped to keep down the internal temperature.

Some plants use sodium nitrate and some potassium nitrate as the source of nitric acid for the chambers. The sodium sulphate formed in the first case is difficult to get rid of, whilst the potassium bisulphate can easily be converted to the neutral sulphate and sold at a price which materially helps to reduce the cost of production of the sulphuric acid.

The Hydrochloric-acid Industry.

The demand for hydrochloric acid appears to be greatest in the Bombay and Ahmedabad district, and a total for all India of about 900 tons per annum appears to be the maximum demand. The type of plant used varies from the old-fashioned horizontal cylindrical retort, with Woulffe bottles as absorption elements, to the latest pot and muffle furnace type with cisterns and towers. The former turns out the best class of acid, but the latter, with certain modifications, should produce equally good acid. The manufacture of hydrochloric acid is bound up with the demand for Glauber salts and sodium sulphide, and it requires the greatest skill and knowledge of the market requirements to so produce that the loss on one part of the manufacture does not absorb the profit on the others.

Sulphates and Nitric Acid.

Glauber's salt, Epsom salts, and copperas are made in five factories, four of which we in England would term only manufacture on the experimental scale. All these chemicals are subject to keen competition from the German imports, and it is very doubtful if any profit is made on these products in any one of the above factories.

Nitric acid is made in four factories, and is about to be produced in one other. The retorts are cylindrical, horizontal, and of the modern three-piece vertical type. Decolourising in one factory is done by steaming the acid in jars. Earthenware and silica condensers are usual. The demand is greatest in the Madras district, the bazaars of Calcutta and Bombay coming next. A pure acid is not demanded, and the total quantity consumed does not appear to be more than one hundred tons per annum.

The manufacture of T.N.T. has been mooted, but the scheme seems to have been abandoned, as has also the contemplated production of diazo compounds for the dyeing establishments. In addition to shortage of the necessary raw materials, the activities of the German colour companies have no doubt had a lot to do with the decision that the game was not worth the candle.

Zinc chloride is most in demand on the Bombay side of India, due to the numerous cotton mills established in this presidency. A production of two hundred tons per year of concentrated chloride meets the present total consumption. A small quantity is used as a timber preservative, as a protection against the ravages of the white ant

Aluminous Compounds and Sodium Sulphide.

There is a large consumption of aluminium compounds in India, waterworks and paper mills being the chief purchasers, with textile mills coming next. Alum is made by two factories, their output being about 100 tons per annum, whilst a third is about to commence operations. The process used is complicated and costly, and needs improvement. Sulphate of alumina is made in two forms—crude cake, from Indian bauxite, and a purer form, 14/15 per cent. Al_2O_3, by redissolving the crude cake, settling and concentrating. No iron-free or neutral material is made, although the demand is of the order of 6/8,000 tons per year, and likely to increase.

Sodium sulphide is in good demand, and is certain to increase as dyehouses and tanneries increase in number. None is made in India, but one factory is about to make the attempt so far as concentrated liquor is concerned. Obviously this is bound up with the supply of sodium sulphate, of which there are two sources of supply—viz., hydrochloric acid plants, and direct from sulphuric acid. It is true that in the alkaline earth of Bihar, sodium sulphate is found, but the cost of extracting and concentrating is prohibitive.

Caustic soda and sodium carbonate are in great demand, but unless an enormous protective duty is placed on these products it is not in the least likely that their manufacture in India will be attempted for many years to come.

Aniline in Fuel Oil Analysis.—Gravimetric and volumetric experiments on synthetic mixtures have shown, state D. Holde and S. Weill (*Brennstoff-Chem.*, 1923, 4, 177–179), that wet aniline dissolves coal-tar oils completely from mixtures of these oils with mineral oils, leaving the latter unaffected, so that it can be used to determine the percentages of tar oils present in mixtures. According to an abstract of their paper in the *Journal of the Society of Chemical Industry*, a little aniline is dissolved by the mineral oil, but it can be removed thence and from the solution of the coal-tar oils by treatment with hydrochloric acid. Rosin oils are somewhat soluble in wet aniline, and if an excess of the latter be employed, they can be dissolved from mineral oils quantitatively. Further, fatty oils can be separated from mineral oils by treatment with an excess of dry aniline. Aniline has the advantage of being much less poisonous than dimethyl sulphate, which up to the present has been used to separate various classes of oils.

THE WORLD'S TRADE IN ARTIFICIAL SILK.*

RAPID EXPANSION BOTH IN EUROPE AND AMERICA.

THE use of artificial silk has expanded with such rapidity as already to have a direct bearing on the situation in real silk and a potential influence on both the cotton and wool markets. As early as the eighteenth century attempts were made to discover a substitute for raw silk, but it was only with the perfection of the nitro-cellulose process in the eighteen eighties by Count Hilaire de Chardonnet that a commercially successful fibre was produced. Upon the Frenchman's experiments as a foundation the artificial silk industry has been expanded until to-day the world produces over 70,000,000 pounds of artificial silk, an amount considerably in excess of the commercial crop of real silk.

General Survey of World Production.

Estimates of pre-war world production of artificial silk vary considerably, a Belgian authority quoting 26,000,000 pounds as the probable 1914 figure, an increase of 21,600,000 pounds from the 1902 estimate or approximately 500 per cent. Considered in the light of an average real silk output of only 64,000,000 pounds for the years 1910 to 1914 the significance of artificial silk in the textile field is manifest. Less striking but very significant is the increase which the last eight years have brought. While accurate information on production in most countries is unavailable, estimates secured by the United States Department of Commerce indicate a world production for 1922 in excess of 70,000,000 pounds. This figure may be compared with a world real silk production of only about 63,000,000 pounds in 1922. Belgium, whose 1921 artificial silk production was over 4,000,000 pounds, largely expanded its output in 1922, and France, which was credited with a daily production of 9,000 pounds in 1920, more than tripled its output last year. Germany, too, enjoyed a remarkable revival, its 1922 production being about 200 per cent. larger than that of the previous year. Other important producers were Switzerland and Italy, each contributing last year about 6,000,000 pounds to the world's supply. Both Japan and Poland furnished over a half million pounds, the Netherlands double that amount and the production of the United States expanded over 60 per cent. in the year.

Growth in the British Trade.

British trade in artificial silk, though of considerable importance before the war, is not recorded separately in official statistics. However, in 1914 Great Britain sent 1,300,000 pounds of artificial silk yarns to the United States alone, according to American statistics of imports. In 1919 American imports of British yarns had dropped to 196,900 pounds or only 15 per cent. of 1914 imports, but by 1921 they had risen to 56 per cent. of pre-war figures. Last year's imports showed a considerable advance over 1919 quantities, but amounted to only 37 per cent. of 1914 imports. The marked decline in American imports from Great Britain as compared with 1921 takings was only part of a general decrease of 43 per cent. in U.S. imports from all countries.

Although most of the British yarns are made by the viscose process, since the war the cellulose acetate process has been developed under Government subsidy. The product has a high lustre and elasticity, is apparently waterproof and sun fast, and is marked by its similarity in appearance to natural silk. This type of silk is spun largely in the fine counts, the average running around 40-50 deniers. However, acetate silk is so costly as yarn and so expensive to convert into the finished product that it holds a field rather separate from that of other artificial silks and is more nearly a competitor of raw silk.

The Belgian and French Positions.

Belgium, which before the war furnished about one-fourth of the world's supply of yarns, had dropped to a position of practical insignificance by 1919 due to the fact that the industry was largely destroyed by wartime confiscation of machinery. It has since recovered volume remarkably, net exports amounting to 543,600 pounds in 1922.

The trade of France in artificial silk yarns was less important quantitatively before the war than it is to-day. However, its position has changed considerably since the war, French imports now exceeding exports. From net exports of 190,000 pounds in 1909 (France imported no yarns at that time) its trade rose rapidly till 1913 when it sold 1,400,000 pounds abroad. 1919 found France importing considerable quantities from both Switzerland and Belgium, its own industry being apparently unable to supply all the demands of the domestic market. In 1921 it resumed its old status as a net exporter, but in 1922 imports exceeded exports by 315,000 pounds. However, the volume of 1922 trade showed a considerable increase over the preceding year, especially in imports, which totalled 3,700,000 pounds against 1,900,000 during the year 1921. Most of the French yarn is spun by the viscose process. An interesting development has taken place in the establishment at Lyons of an artificial silk mill capitalised at 15,000,000 francs to produce viscose silk, the promoters including many well-known textile manufacturers.

The German Output and Trade.

In 1913 production of artificial silk in Germany was equal in value to 28 per cent. of total European production, according to the estimate of the Berlin National Office of Artificial Silk. Although we have no standard by which to measure comparatively the importance of its output, it is manifest, taking value as the basis, that the product of the German mills was very appreciable even before the war. Production in 1919 amounted to 3,500,000 pounds. By 1921 it had more than doubled, and the 1922 output is expected to show an increase over 1921. Germany has always been a net importer of artificial silk yarns, although exports before the war were considerable and are to-day. Present imports are well under the pre-war average, Belgium supplying most of the imports during 1922 as it did before the war. Second and third places are now occupied by Switzerland and Italy, supplanting Austria-Hungary and France which prior to 1914 supplied substantial quantities. However, Switzerland is now the chief customer for German artificial silk yarn exports, the United States and Czecho-Slovakia assuming important places. At present, a number of firms formerly producing military explosives are making artificial silk, and German inventive ingenuity is being turned to perfection of the processes. Among other inventions, a vegetable substitute for spun silk or schappe is said to have been discovered.

From a minor position before the war, Italy has now taken a place of importance, net exports for 1922 aggregating over two million and gross exports over three million pounds of artificial silk yarns. As a net exporter, Italy holds a position of pre-eminence on the Continent and as a gross exporter is surpassed only by France. Switzerland is the leading customer, the United States ranking second, while Belgium is now the principal source for Italian imports.

The Rapid Rise of Switzerland and Holland.

The rise of Switzerland in the artificial silk field was accelerated by the war. Before 1913 an exporter of considerable quantities of yarn, it had made substantial progress, until in the year 1922 it exported 1,900,000 pounds, principally to Great Britain, the United States and Spain. Its advance during the war was due in no small measure to its favourable position in relation to the Central Powers and its status as a neutral. Great Britain is at present the best customer. Though it exports large quantities of yarn, most of its output is consumed by the domestic industry which produces a variety of goods. With the exception of the years 1920 and 1922, Switzerland has been a consistent net exporter not only in the years just prior to 1913, but since the end of the war. Last year saw a change from 1921 net shipments of over 1,000,000 pounds to net imports of 70,500 pounds in 1922, the reversal being due in part at least to a quickened home demand.

The rise of the Netherlands to importance in the European trade has been very rapid since 1919. In that year 70,000 pounds of yarns were imported chiefly from Switzerland, but in 1922 imports had reached 291,000 pounds, an increase of 316 per cent. The principal source of supply was Germany. Exports in 1922 likewise showed a remarkable increase amounting to 284 per cent. over 1919 figures which stood at 456,000 pounds and net exports for the same period made a 278 per cent. advance. It is reasonable to suppose that the Netherlands, like Switzerland, benefited by its status during the war, but quantitative comparisons are impossible since pre-war statistics do not report artificial silks separately.

Even Japan, which supplies over half of the world's real silk, has been invaded by the artificial silk product. Prior to 1912 Japan carried on no trade in artificial silk, but in that year it imported 162,000 pounds, the countries of

* Statistical data from *Commerce Monthly*, the official publication of the National Bank of Commerce in New York.

origin not reported. By 1916 its imports had dropped to 42,000 pounds, but rose again and stood at 75,900 pounds in 1919, derived principally from Switzerland and Great Britain. They have continued to rise steadily and in 1922 totalled 224,600 pounds.

While the artificial silk yarn trade of the principal European countries and of Japan bulks large, both quantitatively and in value, of greater importance are their operations in manufactured products containing artificial silk, either alone or in combination with other textiles. These invisible imports and exports may be regarded as of very substantial bulk and value. Especially is the trade of France and Switzerland distorted unless exports of manufactures of artificial silk are associated in mind with the trade in yarns.

Growth of the Artificial Silk Industry in America.

The year 1911 witnessed the beginning of the artificial silk industry in the United States, the establishment of an organisation operating under the viscose process marking the launching of a new fibre in the American textile trade. From a modest output of 320,000 pounds in 1911 this factor alone has increased its production to a total estimated for 1922 at 19,900,000 pounds. Other producers have entered the field, operating under the Chardonnet, acetate and cuprammonium processes, and production of yarns in 1922 totalled 24,406,000 pounds. Unsettled transit conditions and Europe's war demand for its domestic output caused a reduction in U.S. artificial silk imports from 2,700,000 pounds in 1915 to 93,000 pounds in 1918. After the war they reacted sharply, reaching a peak in 1921 when the United States took 3,700,000 pounds. Of this Italy supplied 771,000, Switzerland 720,000, Great Britain 714,000, and Belgium 637,000 pounds. U.S. imports reflect very accurately the ascendancy which Italy and Switzerland gained as a result of the war, imports by the United States for the fiscal year 1914 standing at 60,000 pounds from Italy and 158,000 pounds from Switzerland. The Netherlands sent 218,000 pounds in 1921 against 5,000 pounds in 1914, figures which bear eloquent witness to its progress as an exporter.

Due in part to strong competition from the domestic product in 1922, U.S. imports of yarns decreased over 40 per cent., imports from several important sources showing material declines. Belgium supplied only a little over one-third of its 1921 quantity and the Netherlands but one-half, while France sent last year only 15 per cent. of the total exported to U.S. in 1921. From Germany and Austria, on the other hand, decided advances in importations were made. American receipts from Austria rose from nothing in the period 1919-21 to 29,600 pounds in 1922, approximating 1914 exports to the United States. Imports from Germany were 63 per cent. greater than in 1921, that country being the only large producer to increase its supplies to America last year.

The following table shows the trade of the United States in artificial silk yarns, accurate figures for manufactures not being available. Trade in finished goods, pure and mixed, is known to be very large, but the artificial silk content cannot be dissected out.

Trade of the United States in Artificial Silk Yarns, Threads, and Filaments, in Pounds.

—	Production.	Imports.	Exports.	Re-exports.	Net Imports.	Available for Consumption.
1913.....	1,566,000	2,304,795	—	6,354	2,298,441	3,864,441

* Not reported separately.

Price Stability an Aid to the Industry.

Perhaps the most conspicuous fact in the artificial silk situation in America is the price of the material, which is now less than one-third of the price of raw silk. However, even more important than the position of the price to-day in relation to real silk is the stability of the quotations for artificial silk. While during the last three years raw silk has pursued an erratic course between a maximum of 16.85 dollars and a minimum of 5.00 dollars, artificial prices have fluctuated little and have held firm for many months at low figures. With real silk to-day at nearly 9.00 dollars and replacement prices a matter of speculation, the appeal which artificial silk is making to the American manufacturer is apparent, and the far-sighted action of the producers in keeping artificial silk prices steady in what has long been practically a "seller's market" has further advantaged the manufacturer of silks by supplying an alternative material for the virtually monopolised real silk. How valuable this alternative has been is illustrated by the fact that domestic production of artificial silk in 1922 was equal to 55 per cent. of American imports of raw silk, with artificial stocks negligible.

Even with the amazing increases in production of artificial silk the supply has not kept pace with the demand which has steadily increased and broadened. While the production of real silk responds only tardily to demand, the circumstances of artificial silk production allow for elastic regulation of supply to demand. However, the large initial capital costs, the necessity for quantity output to make production profitable, the relatively low profits per pound and the great mechanical and technical difficulties inherent in the industry have kept the units relatively large. In America and elsewhere the textile men have fostered the industry, realising its potentialities in protecting them from centralised control of raw silk.

ARSENIC SITUATION IN AMERICA.

STATISTICS FOR FIRST HALF OF 1923.

FIGURES are now available of the U.S. output and sales of arsenic products during the first half of 1923. An increase of 25 per cent. over the 1922 output is shown, but the estimate made by the Geological Survey last Spring of 22,000 tons of white arsenic has been proved to be too high. According to the *Oil, Paint and Drug Reporter*, the actual figures show that white arsenic was produced at nine plants operated by six companies in the United States during the first six months of 1923. The sales during the first five months of the year and the estimated sales in June amounted to 6,035 short tons of refined arsenic, valued at 8.36 cents to 15 cents a pound, and 1,183 tons of crude arsenic, valued at 7.43 cents to 10 cents a pound. No large stocks of arsenic remained at the works, and the prospect is good that production during the last half of the year will equal or exceed that during the first half.

Imports of White Arsenic.

The imports of white arsenic during the first three months of 1923 amounted to 2,694 short tons, valued at 447,645 dollars. During this period Germany shipped the largest quantity of white arsenic—588 short tons, valued at 117,549 dollars—and was followed by Japan, with 513 tons, valued at 78,869 dollars. Other countries, named in order of size of shipments of white arsenic to the United States, were France, Belgium, Mexico, England, Canada, Dominican Republic, Brazil and Australia. If the imports of white arsenic continue during 1923 at the rate of 800 tons a month the total available supply in the United States for the year will be about 21,000 tons.

No red or yellow arsenic sulphide was reported to have been produced in the United States during the period considered, but imports of these products amounting to 452 tons were received from China in January, 1923, having shipped through a port of British India. Smaller quantities were shipped from France, Germany, England, Belgium, Canada and Japan. Some metallic arsenic was received from Germany in February.

Supplies in the United States.

The Western States have the largest undeveloped deposits of arsenic, and these are now receiving attention. Several new plants for the direct treatment of arsenic ores are contemplated. The deposits of Montana at present furnish the largest supply of arsenic, producing more than 4,500 tons of white arsenic annually.

Nevada has the largest available supply of arsenic above ground in the United States. At Eureka there is a great accumulation of speiss from smelting operations that were carried on in the seventies. During the first six months of 1923 this speiss dump was drawn on by the smelters in Utah and Washington at the rate of 2,000 tons a month. The speiss carries an average of 30 per cent. of arsenic, and when all metallurgical losses are deducted it probably provides 3,500 tons of white arsenic annually. At Toulon, near Lovelock, Nev., the Toulon Arsenic Co. operates the only arsenic plant in Nevada.

THE DEVELOPMENT OF THE FAST DYE INDUSTRY.*

THE GROWING IMPORTANCE OF THE VAT COLOURS.

THE production of fast dyestuffs has developed along a few well-defined lines. Among wool colours there are the acid alizarine dyestuffs and the after-chrome dyestuffs; among cotton colours, the vat dyestuffs, sub-divided into anthraquinone and indigoid dyestuffs, and it is a point of some significance that the more important fast colours for both wool and cotton are derived from anthraquinone.

The oldest vat dyestuff, indigo, was long considered the last word in fastness, but is now considered only of medium fastness. Soon after the commercial synthesis of indigo came the discovery of indanthrene and flavanthrene by Bohn in 1901. The discovery of the property of the anthraquinone molecule of yielding readily oxidised leuco compounds led to the preparation of a whole new series of dyestuffs, and development for the last twenty-five years has proceeded along two lines, that of dyestuffs constitutionally similar to indigo—the indigoid dyes—and that of dyes containing the anthraquinone molecule. A third and growing series is that of the carbazole colours, represented by the hydron colours of Cassella, though these are sometimes classed as sulphur colours.

Some idea of the progress made with vat dyestuffs may be gathered from the following figures, from which synthetic indigo is excluded, though its substituted derivatives are included. In 1901 there was one firm producing one dye (indanthrene); in 1906 there were three firms producing 20 dyes; in 1910 there were six firms producing 80 dyes; in 1914 there were six firms producing 206 dyes; and in 1922 there were ten firms producing 250 dyes (excluding U.S.A.). The total consumption of German imported vat dyes, excluding indigo, in Great Britain in 1913 was 294 metric tons, comprising one-sixtieth of the total imports. The imports in 1922 amount to 126 tons, comprising one-eighteenth of the total imports. To this we may add 100 tons as representing British production, so that the total consumption in 1922 is almost equal to that of 1913 in vat dyes, and that in a year of very bad trade conditions. The proportion of vat dyes consumed shows an enormous increase.

Principal Classes of Vat Colours.

The anthraquinone series include the Indanthrene, Algol, Cibanone, and some of the Helindone colours. Among the indigoid class are the Ciba, Thioindigo and Thioindone, Alizarine Indigo colours, and the various bromindigos, brilliant indigos and methyl indigos. These are substitution products of synthetic indigo. The indanthrenes are the most popular on account of their excellent fastness, in which, generally speaking, they surpass all the other groups, and also by reason of the comparative simplicity of their application. Simplicity of process is an important factor in regard to demand, and the adoption of two standard processes—one for hot dyeing colours and another for cold dyeing colours—has probably operated in favour of the indanthrene colours over the other groups, in which each dye requires a different process.

The origin of the name indanthrene is interesting. Being the first vat dye to be discovered after indigo, and its colour being similar, justified the "ind" portion of the name, and the fact that it was derived from anthraquinone gave the "anthr." and the termination "ene" completed the name. The anthraquinone vat dyes in general give very brightly-coloured vats, whereas the members of the indigoid series all give yellow to yellowish-brown vats. Further, the latter are suitable for dyeing animal fibres, whereas the anthraquinone dyes are, with few exceptions, applicable to vegetable fibres only. Generally speaking, also, the indigoid dyes are less fast than the anthraquinone dyes. Though the Thioindigo, Helindone, and Ciba colours are suitable for wool, they do not appear to have been greatly used for this purpose, though a large amount of khaki was dyed with these colours in America during the war.

For a long time the Badische Co. were without rivals in the domain of vat dyes. They appeared as pioneers in 1901-2 with Indanthrene Blue RS, followed rapidly by Indanthrene Yellow G (Flavanthrene) and Indanthrene Blue GC, which is fast to chlorine. In 1904 the GCD brand appeared, followed by Violanthrene, a dark blue. The years 1905 and 1906 saw important developments in the indigoid series in the production of Friendlander's Thioindigo Red B, by Kalle, and of Indigo MLB/T and R—directly substituted brom-indigos. The first Ciba colours made their appearance in Switzerland at this time also—Ciba Blue, Heliotrope, and Violet. The range of dyestuffs available then, when the first guaranteed fabrics (Sundour fabrics, first made by the British firm of Morton's Sundour Fabrics, Ltd., in 1906) were produced, was very small, and was practically confined to blues and greens, the latter being obtained with mixtures of Indanthrene Blue and Yellow, the Yellow being quite fast in mixtures, but not particularly so in self-shades. Reds were dyed with alizarine in very deep shades.

Competition Amongst Manufacturers.

Not until 1907 can competition in vat dyes be really said to have commenced. In that year Bayer introduced the Algol colours—Blue CF and 3G (dihydroxy indanthrene), Green B (di-amino dibrom indanthrene), and Red B; and Kalle brought out Thioindigo Scarlet. The first Helindone and Cibanone colours appeared in 1908, and the Hydron Blues in 1910. Additions were rapidly made to all classes, and by 1914 there were about 180 authentic vat dyestuffs on the market. The progress can be gauged from the following table—

Groups.	1902.	1906.	1910.	1914.	1922.
Indanthrene	2	10	27	51	55
Algol	—	—	20	33	35
Helindone	—	—	12	36	45
Thioindigo	—	1	7	20	26
Ciba	—	3	7	17	26
Cibanone	—	—	5	5	19
Hydron	—	—	2	6	31

Progress in the domain of vat dyes has not followed quite the same lines as in other classes of dyestuffs. In most cases the introduction of a new dyestuff by one firm is immediately followed by new competitive products—which may be new dyes or mixtures—by rival firms. In all cases the products are variants on the same chemical constitution. Among vat dyes, however, the rival manufacturers each pursued a separate main line of research. Thus the Badische Co. concentrated on the condensation of anthraquinone nuclei in the production of compounds such as indanthrone, flavanthrone, pyranthrone, and violanthrone, and the anthraquinone acridones; the Bayer Co., on the other hand, devoted most attention to comparatively simply constituted acylamino anthraquinones and anthrimides. The first Algol colours were, however, substituted Indanthrenes; while certain of the Indanthrene colours belong to the anthrimide class. The Cibanone colours are complex products of fusion of simple anthraquinone derivatives with sulphur. The Helindone range was mixed; some were allied chemically to the main Algol type; the remainder to the Thioindigo colours of Kalle. Regarded from another point of view, the Badische Co. devoted their attention mainly to hot dyeing colours, the Bayer Co. to cold dyeing colours.

The vat colours have to be considered more by groups than as individual colours, and the chemical properties of the groups differ so much that great discrimination is necessary in choosing suitable dyestuffs for mixing together. In the early days the range was so limited that dyers had to confine themselves to the products of one firm, but no difficulty is now experienced in choosing suitable colours for working together. Thus there are on the market to-day 41 vat blues (53, including Indigos), 25 violets, 28 yellows, 14 oranges, 66 reds, pinks, bordeaux, etc., 13 greens, 27 browns, 8 olives, 12 greys, 19 blacks. To-day the total number listed is about 460, and post-war development in the production of vat dyes is mainly the development of production in countries outside Germany. New vat colours have been very few, though there are recent signs of activity. The greatest advance has been made in Cassella's range of Hydron colours, to which about twenty additions have been made, covering the whole range of the spectrum. Scottish Dyes, Ltd., have succeeded in remedying the deficiency of a bright vat green. Their new product, Caledon Jade Green, which is probably the forerunner of others, stands in the first class, along with the Indanthrene Blues, for fastness.

* Abstract of paper read by Mr. J. I. M. Jones before the West Riding Section of the Society of Dyers and Colourists in Bradford on March 1. From the complete paper in the *Journal* of the Society (July, 1923).

German Post-war Developments.

An important post-war development in Germany, which is a direct outcome of the merging of all the big dye interests, is that the manufacture of any particular dyestuff is no longer confined to one firm. Thus we find Indanthrene Yellow G appearing as Algol Yellow GBA and Helindone Yellow JG; Indanthrene Violet RR as Helindone Violet J2R, etc. This has also spread to Switzerland, and the Society of Chemical Industry in Basle is now producing Indanthrene Blue RS and GC under the name of Cibanone Blue RS and G, and Indanthrene Violet R under the name of Cibanone Violet R.

A more interesting development, and a distinct step forward in the fast dye crusade is the action of the Badische Co. in re-naming all the vat dyes manufactured by them (including Algol and Helindone dyes) according to a definite system based on their fastness. The name Indanthrene is retained for the dyes of the first class, and Anthra for those of the second. Thus the Anthraflavones now become Anthra Yellows; Indanthrene Bordeaux B becomes Anthra Bordeaux R; Vat Heliotrope R becomes Anthra Bordeaux R; Vat Red B becomes Anthra Red B. Further, the designations of many of the original colours have been altered to indicate special properties. All cold dyeing colours, for instance, have the letter K added. Thus Indanthrene Red BN becomes Indanthrene Red RK; Algol Yellow R becomes Indanthrene Yellow GK; Algol Brilliant Orange FR becomes Indanthrene Orange RRK; Algol Blue K becomes Indanthrene Blue RK; Helindone Yellow RN becomes Indanthrene Yellow RK.

This is a very desirable step. Vat dyes are becoming more and more firmly established and widely used every year, and as there are good and bad vat dyes the indiscriminate inclusion of the latter among reliable products is apt to be misleading. There are over 2,000 recorded chemical compounds which have vat dyeing properties, of which little more than 10 per cent. find their way into commerce, either on account of high cost, difficulties in manufacture, or weakness in some or other of their fastness properties. An example of a bad vat dye is Helindone Scarlet S, which gives an exceptionally fine shade, which, unfortunately, is neither fast to light, chemic, nor rubbing.

British Progress in Vat-dye Manufacture.

The efforts made in the manufacture of vat dyes in this country have primarily been directed to the production of the well-established German colours; and new products have naturally been few. In the sphere of vat colours the first firm in the field was Solway Dyes, now Scottish Dyes, Ltd., who produced Indanthrene Yellow G and Blue RS under the names Caledon Yellow G and Blue R as early as 1915, followed by Indanthrene Dark Blue BO, Green B, Brown B, Black B and Violet R in 1917, and Indanthrene Red BN, Violet RN, and Violet RR in 1918. The output was, of course, limited, and the quality not all that could be desired, but time has remedied both these defects. The manufacture was also taken up by British Dyes, Ltd., with the Chloranthrene and Duranthrene colours; L. B. Holliday, with Hydranthrene, and recently the British Alizarine Co. with the Alizanthrene colours. The development in Britain is illustrated by the fact that in 1920 there were 17 chemically different British vat dyes available, and in 1922, 33. These products cover the whole range, and include the pick of the German vat dyes, and the quality on the whole is up to the German standard. In many cases, indeed, British manufacturers have succeeded in producing purer products than the German analogues.

The number of dyes of various brands produced in 1922 is as follows—

Caledon	20	Hydranthrene	6
Duranthrene	13	Alizanthrene	3
Durindone	6		

In America the Newport Chemical Co. and the Du Pont Co. are also manufacturing a wide range of reputable vat colours.

At present, on account of price, the really fast dyes can only be used for special purposes. The public are continually demanding faster products, but are not always prepared to pay the cost. The need is therefore to enlighten the public more as to the value of vat dyes, and so increase the demand. In this connection it is interesting to note that a retail establishment has recently been opened in Berlin, known as Indanthrene House, which deals solely in goods dyed with Indanthrene colours—shirts, dress materials, gowns, brocades, etc.

AMERICA AND THE GERMAN PATENTS.

PROGRESS OF THE SUIT AGAINST THE CHEMICAL FOUNDATION.

THE hearing of the evidence in the lawsuit which the American Government is taking against the Chemical Foundation Inc. was concluded on July 23. It will be remembered that the claim of the Government is for the return by the Foundation of 4,800 siezed German dye and chemical patents purchased from the Alien Property Custodian in 1919 for 250,000 dollars. The amount of testimony brought forward on both sides has been enormous and the proceedings have, on many occasions, been marked by considerable acerbity. The summing up by the counsel for both sides will not be heard until October 9, and it is believed that no matter what the final judgment on the case will be, the loser will appeal against the decision.

Experiments Performed by Order of Court.

The final hearings of the evidence were remarkable in that several witnesses for the Government who testified to it being possible to make certain chemicals commercially having no other information available than that given in the German patent specification, were ordered by the Court to perform these preparations under conditions of close supervision. Thus Dr. L. Freedman, a chemist formerly in the service of the Calco Chemical Company, was ordered to prepare cincophen by following the German patent formula. The test, which occupied 26 hours, took place in the laboratories of Swarthmore College, Wilmington, Delaware, and was under the supervision of observers for the plaintiff, defendant and the court. Dr. Freedman produced his sample, but was afterwards subjected to fierce cross-examination in which it was alleged that the yields obtained were useless, the product was not of marketable quality and that Dr. Freedman had not followed the German method as closely as he should have done.

Mr. W. G. Christiansen of the Harvard Medical School, and Dr. Chester N. Myers of the Metz research laboratories, both stated that they had made salvarson by following the German specifications reasonably closely, but here again it was held by the Counsel for the Foundation that material improvements upon the methods given in the patents had actually been made.

JAPANESE MATCH INDUSTRY.

A DECLINING TRADE.

THE match trade, in which Japan has taken in the past full advantage of cheap woman and child labour and freedom from factory legislative restrictions, has, nevertheless, not established itself in such a way as to show signs of permanence, states the Kobe correspondent of the *Chamber of Commerce Journal*. During the military occupation of Siberia it seemed sufficient reason for depression in the match trade that poplar wood could not be obtained from Siberia. Now that it is possible to trade again the situation seems to be in no way improved. Matches were exported during the first two months of the year to the value of only Yen 1,827,000, against Yen 2,621,000 in the corresponding two months of the previous year. The absorption of the Japanese match trade in a general world combine is only a matter of time. Negotiations have been going on for years now. The Japanese had their best opportunity in 1919, when a representative of the Diamond Company was over there from America, and the deal was on the point of being concluded on very handsome terms. But in the post-war boom the Japanese felt that the possibilities of trade expansion were unlimited, and put up their price. Representatives have been there since that date, but the Japanese manufacturers cannot now bring themselves to face the facts of the change in the situation. It will probably end in the combine—or the American branch of it—setting up a big factory in China, and leaving Japan only her domestic trade instead of the big Chinese zone that she could have secured in 1919.

Levers Purchase Norwegian Whaling Company.—The Norwegian whaling company, Norge Larvik, has, according to the *Aftenposten*, been transferred to Messrs. Lever Brothers for about seven million crowns.

THE OILS AND FATS INDUSTRY.*

SCIENTIFIC AND TECHNICAL PROGRESS IN 1922.

IT has been a very general opinion that the world's consumption of margarine would be largely increased by the greatly enhanced appreciation of its value as a foodstuff, arising from the experience gained of it during the war years, when it was practically compulsorily used as a foodstuff. There can be no doubt, however, that butter is still esteemed as the prime fatty food for man, and that even a large difference in price between it and its substitutes is no very appreciable aid to the increased consumption of the latter products. It is well known that our margarine factories now are working, in total, to little more than one-third of their maximum output, and that the same condition exists both on the Continent and in the United States. United States Government statistics show that during the financial year ending June 30, 1922, only 83,881 tons of margarine was produced in that country, as compared with over 125,000 tons produced in 1921. It has been asserted frequently that large quantities of maize and soya-bean oils are used by American margarine manufacturers, but the statistics of the Commissioner of Inland Revenue clearly show that this is not the case, since in 1921 maize and soya-bean oils formed only 0.4 per cent. and 0.2 per cent., respectively, of the total fats employed.

From the point of view of Imperial commerce it is gratifying to find that though our total import of linseed for eleven months of the year is lower than that of 1921 by no less than 110,000 tons, we have received from India over 140,000 tons, as against only 36,000 tons in the same period of 1921. There is little doubt that the absence of Russia as a producer is having a large effect upon the market for linseed. This is in considerable measure compensated for by an increased output from the Argentine, where it is estimated that a record crop of 1,500,000 tons will be available this year. This output, along with an increased internal production in the United States of no less than 300,000 tons, should make for lower prices and larger consumption in this country. The amount of cottonseed imported from India in 1922 was almost four times as great as that received in 1921, but much more is available from that source, and it is to be regretted that transport conditions in the country of its origin are probably the prime reason for so small a proportion of the actual production being utilised as a source of one of our most valuable oils.

Shea Butter and Fat.

As a possible, but very largely unworked, source of oil there is probably no greater in the world than that provided by the immense forests of *Butyrospermum Parkii*, which stretch behind the oil-palm belt in West Africa. In the form of shea butter the fat from the seeds of this tree is quite largely used in native cooking, and occasional shipments of both seeds and fat are made to Europe. Its use, however, has been limited by the peculiar rubber-like odour of the fat, and still more by the presence in it of a very variable and frequently large amount of unsaponifiable matter (up to 10 per cent). There is some reason for assuming that the amount of unsaponifiable matter is governed either by variety in the species of the trees, or by climatic or other conditions governing their growth. It is interesting to find that the Agricultural Departments of the West African Colonies are investigating the many problems which present themselves in connection with this product. Work has already been begun in Nigeria, and a report from the Gold Coast Colony, which states that shea trees now existing in that country are capable of producing 260,000 tons of butter annually, indicates that preliminaries for carrying out this work are now well advanced.

The development of coconut plantations on the communal system in the Gold Coast Colony will also be watched with much interest. That copra can be produced there is of course well known, and the success of this experiment seems assured if the phenomenal success of cacao-growing in the country is to be taken as a guide. The plantations now begun are expected to be in full bearing about 1935, but copra will, of course, be produced before that time. Besides the above evidences of keen Governmental interest in the oils and fats industries, and those remarked upon last year, it now appears that the Brazilian Government is so far interested in the oil-seed possibilities of the country that, after having had a complete survey of the northern part of the country made, it is recommended by the Department concerned that experimental stations be established at Para and Bahia. After a survey of the southern states is completed, it is probable that similar stations will be established in that area.

Preparation of Fatty Acids from Hydrocarbons.

The preparation of fatty acids from hydrocarbons still receives a great deal of attention, but little progress is indicated in the published details of the work. Much of this is in the form of patent specifications which cover processes for the preparation of mixtures, more or less suitable for use in the manufacture of soap, the raw materials being usually hydrocarbon residues or tars. Some of these processes are of a most elaborate nature, and seem of very doubtful commercial utility. H. Siebeneck, without attempting to distinguish the individual products of the reactions which take place, has investigated the oxidation of paraffin wax by means of air or oxygen at a temperature of about 135° C. Products of cracking were found in the early part of the experiments, but later, wax-like products were produced, the quantity of which, apparently, increased up to about 33 hours' heating. Thereafter, the ester value, which had increased to an extent equivalent to 70 per cent. of esterified acids, fell to 49.16, a change which was accompanied by a very appreciable slowing of the reaction and an increase in viscosity of the products to about five times the original value.

A. H. Salway and P. N. Williams (*Chem. Soc. Trans.*, 1922, 121,1343), who have investigated the catalytic oxidation of hexadecane by means of oxygen in presence of 2 per cent. of manganese stearate, clearly prove that the result of such like oxidation processes is to produce compounds which are as readily oxidised as the substances they produce. They suggest that the paraffin hydrocarbon is probably first converted into a fatty acid, which is then further attacked at several points in the carbon chain, with the ultimate production of a complex mixture of monocarboxylic acids of the fatty series, dicarboxylic acids of the malonic series, together with lactones, lactonic acids, formic acid, and carbon dioxide.

The interesting work of B. H. Nicolet and H. L. Cox (*J. Amer. Chem. Soc.*, 1922, 44,144) on the structure of linolic acid has led them to the conclusion that only two of the four possible stereoisomeric linolic acids occur, at least in important amounts, in linolic acid as usually prepared, these being the trans-trans and trans-cis forms. As the linolic acid examined was regenerated from the tetrabromide prepared from the fatty acids of cottonseed oil, and recognising the possibility of change during this preparation, it cannot yet be finally assumed that the structure of the linolic acid in this oil has been proved.

The Chemistry of Drying Oils.

A large amount of work yet remains to be done before our knowledge of the reactions involved in the drying of oils is complete, but we are carried several steps toward this end by the continued work upon the subject of S. Coffey (*Chem. Soc. Trans.*, 1922, 121, 17) and P. Slansky (*Z. Angew. Chem.*, 1922, 35, 389). It has been already established that the drying of linseed oil can be divided into two stages, an induction period which covers a considerable portion of the total time required for complete oxygen absorption, and a second stage in which the oil, having gelatinised rapidly, passes to its point of maximum oxidation. It has generally been accepted that the increased rate of oxygen absorption which results from the presence of "driers" such as the compounds of lead, manganese, cobalt, etc., in the oil has resulted merely from a speeding up of these processes, but the recent work of Coffey has established the fact that the induction period is so far reduced as to be almost eliminated, whilst the rate of the main oxidation is unaltered. This undoubtedly provides an explanation of the accelerating effect of a drier from the point of view of time, but until it is proved that the resulting "dried" products are the same it cannot be assumed that the course of the oxidation is identical in both cases. Coffey's results strongly support this view, and are corroborated in considerable measure by the previous work of R. S. Morrell. It would certainly appear that in presence of a drier the oxidation of linolic acid is restricted to the absorption of one molecule of oxygen instead of two, and there is probably a similar but more indefinite action in the case of linolenic acid. Such effects as this readily explain the fact that in every case the oxygen

* From article on "Oils, Fats, and Waxes," by Mr. John Allan, of Messrs. Joseph Crosfield and Sons, Ltd., Warrington, in the "Annual Report on the Progress of Applied Chemistry" for 1922. Published by the Society of Chemical Industry.

absorption recorded is lower than that observed when no drier is present, and the reaction surves are different.

Chinese Wood and Perilla Oils.

The fact that about 35,000 tons of Chinese wood oil was imported into the United States during 1922 makes it quite clear that this oil is now extensively used as a substitute for, or in partial replacement of, linseed oil. As both varieties of the species *Aleurites* occur in China and Japan it is highly probable that the imported oil is of mixed origin, and much of the published work on its composition is consequently of limited value.

The extending use of perilla oil, usually in admixture with linseed oil, lends interest to the results of the investigation of the fatty acids of the oil by K. H. Bauer (*Farben Zeit.*, 1922, 27, 2756). These are stated to be a mixture of 12 per cent. of solid acids, mainly palmitic acid, and 88 per cent. of liquid acids which apparently consist of a linolic acid and several geometrically isomeric linolenic acids.

The Fluorescence of Cottonseed Oil.

The fluorescence frequently exhibited by cottonseed oil expressed from seed of Indian and Chinese origin is undoubtedly to be attributed to some constituent of the seed, the presence of which is largely affected by climatic conditions during growth or harvesting. As fluorescent oil gives unsatisfactory results in the refining process, and is therefore depreciated in value as a foodstuff, it would appear to be desirable to ascertain the nature of the fluorescent substance, and establish means either to prevent its development in the seed, or to remove it from the refined oil. With the extension of cotton-growing in our Colonies this defect in oils of Eastern origin is the more worthy of attention.

Spontaneous Combustion of Dry Soaps.

It is well known that the rise of temperature resulting from the rapid oxidation of highly dispersed quantities of fatty acids less saturated than oleic acid or their glycerides, may bring about ignition of the mass. The observation of A. Welter (*Chem. Umschau*, 1922, 29, 151) that the soda soaps of these acids when dry, and in flake or powder form, are equally capable of oxidation and consequently heating, is of distinct technical importance. He quotes a case in which about half a ton of dry powdered soap, prepared from cotton-seed oil, developed such a rise in temperature that in half an hour it had charred to a coke-like mass. Olive oil soaps show no tendency to such an increase in temperature.

The Separation of Solid Glycerides.

The composition of the glycerides of which oils and fats are composed is of much interest, but no satisfactory method has been suggested yet whereby they may be isolated in anything approximating to quantitative measure from the natural mixtures in which they occur. It has been known for a long time that mixed glycerides occur in the various oils and fats, and there can be no doubt that the composition and proportion of these glycerides very markedly affect such properties as the texture and melting-point of solid fats. These properties are of great importance in the manufacture of margarine and other fatty mixtures, but for the present manufacturers are dependent upon experience and the results of trial blends when adjusting the proportion of the constituents of their products. Crystallisation from solvents has been tried as a means of separation by many workers, with very limited success.

Constitution of Montan Wax.

Montanic acid, to which the formulæ $C_{28}H_{56}O_2$ and $C_{29}H_{58}O_2$ have variously been ascribed, has hitherto been regarded as the only acid present in montan wax. By fractionating the methyl ester of the crude acid, H. Tropsch and A. Kreutzer have isolated two acids having the equivalent weights of 410.7 and 439.0, and m.ps. 82° C. and 86°-86.5° C., respectively. It is concluded that the former of these acids, for which the name carboceric acid is suggested, has the formula $C_{27}H_{54}O_2$. It is probably identical with an acid identified in Chinese wax by Gascard. The acid of higher melting point, having the formula $C_{29}H_{58}O_2$, was esteemed to to be pure montanic acid.

The Hardened Fats Industry.

It is interesting to find that the opinion expressed in the Reports of last year that the highly successful application of the process of hydrogenation to fats is now acting as a deterrent to its further extension, is very emphatically supported in a statement by W. Normann (*Z. Angew. Chem.*, 1922, 35, 437), who first discovered the possibility of hydrogenating glycerides in the liquid state. Normann states that the fat-hardening industry in America is in a parlous condition because the margin between the price of liquid oils and that of natural hard fats is less than the working costs of hardening. The author of this statement might well have gone farther by saying that since cottonseed oil, the oil which has been most largely employed in the hardening process in the United States, has been of the same value as lard, and for a period has even been dearer, the possibility of producing from it a hardened fat to compete with lard is obviously impossible.

The rapidity of the technical application of Normann's discovery has been phenomenal, as is made clear by the fact that only three plants were operating in 1910, and they were struggling with the various difficulties of the process, whereas after twelve years no less than about 75 factories have, by their very efficiency, restricted their own operation. Practically no developments of the process fall to be recorded during the year, but there is no doubt that, given the necessary stimulus provided by sufficient price margins in the oil and fat markets, progress will be made on the lines of a continuous process with a fixed catalyst capable of revivification *in situ*, delivering oil without appreciable loss of catalyst.

CANADIAN COBALT PRODUCTION.

OFFICIAL STATISTICS FOR 1922.

We have received from the Dominion Bureau of Statistics at Ottawa the following finally revised statistics on the production of cobalt in Canada during 1922. The major portion of the world's supply of cobalt for almost two decades has been derived from the silver-cobalt-nickel arsenides of the Cobalt district. During 1922 three smelters in Ontario treating ores and residues from this district marketed cobalt oxide, metallic cobalt, cobalt sulphate, cobalt carbonate, cobalt hydroxide, unseparated oxide and stellite (an alloy of cobalt used for high-speed tool metal). The cobalt residues from the cyanide process were mainly treated in Canada during 1922, although some of these, as well as smelter residues amounting in all to 518 tons containing 173,211lb. of cobalt, were shipped abroad for treatment.

Summary of Cobalt Production Statistics, 1922.

Cobalt ores and residues treated or in process, 3,719 tons.
Metallic cobalt content of the above (by assay), 536,400lb.

—	Output of Smelters.		Marketed.	
	Total.	Cobalt Contained.	Quantity.	Value as Reported by Smelters.
	Lb.	Lb.	Lb.	Dollars.
Metallic cobalt ...	106,274	106,274	109,067	282,602
Cobalt oxide	360,495	252,347	398,697	798,271
Mixed oxide.....	86,730	39,023	123,605	99,687
Residues exported..	*	172,311	1,036,000	156,402

CORRESPONDENCE.

*** *We do not hold ourselves responsible for the opinions expressed by our correspondents.*

"DARCO" DECOLOURISING CARBON.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—Referring to the article in your issue of August 10 on "Activated Charcoal," we are surprised to read that your correspondent classes "Darco" decolourising carbon (made from lignite) as a poor filtering medium. The fact that "Darco" is used extensively by the leading oil refiners in America—and our sales in England are increasing—proves conclusively that "Darco" can be used without any trouble whatsoever.—Yours, etc.,

(*p.p.* The L. Martin Company).
G. W. Howing

6 and 7, Stonecutter Street, London, E.C. 4,
August 13, 1923.

ITEMS OF INTEREST.

Insulin Manufacture in Sweden.—The Aktiebolaget Leo, of Helsingborg, is stated to be co-operating with the Lövan chemical factory at Copenhagen for the manufacture of sufficient insulin for all the hospitals in Sweden.

British Coal Output.—The coal output at the mines of Great Britain for the week ended on the 4th inst. was 5,253,600 tons, compared with 5,111,700 tons for the previous week, and 5,121,600 for the corresponding week of last year.

Shellac Substitute Labels.—The U.S. Federal Trade Commission has ruled that it is unlawful to advertise and sell a shellac substitute as shellac or even without clearly indicating the percentage of ingredients used in the manufacture of such substitute.

Tariff Notes.—It is announced that potassium nitrate, B.P., imported into Australia from Germany is now brought under the operation of the Customs Tariff (Industries Preservation Act).—The Polish excise duty on acetic acid has been increased from 3,000 to 6,000 Polish marks per kilog.

Fuller's Earth Deposit in Cornwall. — Following the discovery by Mr. Stephen Clark of a rich deposit of Fuller's Earth on his estate at Treamble, it is expected that a considerable new Cornish industry will be established. One estimate puts the amount of the deposit at 1,000,000 tons, and it has been proved in places to go to a depth of fifty feet. Excavating machinery is already being installed.

Badische Directors Imprisoned.—Two of the directors of the Badische Anilin and Soda Fabrik have been sentenced to six years' imprisonment, and a fine of 150 million marks for having refused to assist in the removal of stocks of dyestuffs and fertilisers seized by the occupation authorities. Other members of the board of directors were each sentenced to eight months' imprisonment and a fine of 140 million marks.

North Broken Hill Scheme.—An Exchange Melbourne message states that Mr. Weir, general manager of North Broken Hill, Ltd., has announced that his company is negotiating the purchase of the British Australian Broken Hill Company's mine and other assets, payable partly in North Broken Hill shares and partly in cash. It is estimated that the British Australian shareholders will receive the equivalent of 23s. 6d. per share.

Commercial Uses of Hafnium.—According to a Copenhagen correspondent of the *Times*, it is expected that it will be possible to use hafnium in the manufacture of audion lamps in wireless telegraphy. A Dutch firm is now investigating the possibilities of its use in this manner. In Norway and Greenland minerals containing hafnium have been discovered. It is hoped that hafnium in great quantities may be found, and an expedition will probably be sent to Greenland to investigate the geological conditions.

The Cellulose Acetates.—In the article on this subject by "Investigator" last week, the following corrections should be made. On page 156, column 1, paragraph 4, line 1, for "benzene" read "benzine." On page 156, column 2, paragraph 5, line 8, for "trichlor-tertiary butyl alcohol (3 per cent.)" read "trichlor-tertiary butyl alcohol (30 per cent.)" In the formula for a 3 coat aeroplane dope given in paragraph 2, column 2, page 156, the weights expressed are in kilogrammes and the volumes are in litres.

American Diabetes Remedies.—It is announced by the American Chemical Society that Dr. Max Kahn of Columbia University has prepared and termed "intarvin" a glyceride of margaric acid ($C_{16}H_{33}COOH$), and has found that the substance is easily assimilated by diabetic patents without appearance of the symptoms of ketosis or glycosuria. Dr. Kahn claims that this is the first time that true margaric acid (as distinct from a mixture of palmitic acid and stearic acid) has been obtained and attributes its assimilation by diabetics to the fact that it is an odd-carbon fatty acid. It is also stated that a process for the large scale and cheap manufacture of margaric acid has been worked out by Dr. McKee, professor of chemical engineering at Columbia University.—With reference to the note on "glucokinin" in our issue of last week, it appears from correspondence in *Nature* that the occurrence and value of insulin-like substances in yeast extracts was observed in this country, by L. B. Winter and W. Smith of Cambridge University, before the discovery was made in America.

University News.—The University of Leeds has appointed Mr. J. A. S. Ritson Professor of Mining in the University, in succession to Professor Granville Poole, who has been elected to a professorship at Armstrong College, Newcastle-on-Tyne.

Canadian Wood Pulp Inquiry.—A Commission has been appointed by Mr. Mackenzie King, Prime Minister of Canada, to investigate the forest resources, with a view to determining the need or otherwise of an embargo on the export of wood pulp.

Russian Requirements of Dyestuffs.—A report from Moscow states that, according to the *Ost Express*, the Textile Trust of Russia has decided to effect its purchases of dyestuffs through the Textile Syndicate. The All-Russian Textile Syndicate is entitled to act independently on foreign markets, and has organised representation in Berlin and London.

Castor Seed Growing in Italy.—A conference has been held at the Italian Ministry of Agriculture to consider the question of growing castor seed in order to furnish lubricating oil for aviation and other transport purposes. It is believed a considerable crop of castor seed could be grown throughout the southern provinces of Italy. At present there is a large import of castor oil from British India.

Personal.—Dr. Percy Longmuir, the director of research to the British Cast-Iron Research Association, has had to resign his post owing to a serious breakdown in health.—Professor Dr. Paul Askenasy has resigned the editorship of *the Zeitschrift für Elektrochemie*, a post which he has held since 1910, and Professor Dr. Erich Müller has been appointed by the Deutscher Bunsen Gesellschaft to fill the vacancy caused.

Liquid Light.—An American chemist claims to have produced a radio-active liquid which when sealed in a bulb can be used for many years. Mr. Guido Blenso, who is credited with the invention, claims, according to reports, that his invention will eventually make coal, oil, and other power a thing of the past, and will be far superior to and more effective than electric light, while it will probably last for ten or fifteen years without attention.

Land Subsidence at Preesall.—There has been a land subsidence at Preesall, near Fleetwood, where the United Alkali Company has brine pumping works A crater has been formed about 120 feet in diameter, and the land in the neighbourhood is gradually sinking A dozen beech trees have gone down the crater, and there is some fear that a farm and out-buildings which are now only a score of yards from the edge of the crater may at any time be engulfed.

Soap Manufacturers' Failure.—The Official Receiver has now issued his report in the liquidation of Sapon Soaps, Ltd., Wharf Road, Cubitt Town, E. The statement of affairs shows as regards creditors liabilities expected to rank £48,119, and net assets £10,979. As regards contributories there was a total deficiency of £347,772. Since the winding-up the Receiver has sold the assets for a sum insufficient to discharge the first debenture claim.

Salters' Institute Awards. — The following awards for 1923-4 have been made by the Salters' Institute of Industrial Chemistry, and approved by the court of the company:—Fellowships are awarded to Mr. T. B. Philip, Mr. W. G. Sedgwick, and Mr. D. T. A. Townend. Fellowships are renewed to Mr. C. G. Harris, and to Mr. J. H. Oliver. Mr. W. Randerson, a Fellow for 1922-3, having been elected to an Albert Kahn Travelling Fellowship for 1923-4, is made an Honorary Fellow for the year.

A New Indicator for Acidimetry.—A very sensitive indicator posessing marked advantages over methyl orange is described by A. Reisenleitner (*Chemiker Zeitung*, August 11, 1923). It is the colouring matter of the wild carrot (*daucus carota*) a plant growing plentifully in Central Europe. The substance is blood red in acid solution and deep green in alkali solution, and the colour change is instant and unmistakeable even when working with decinormal solutions. The indicator is not sensitive to carbon dioxide, but it is preferable to carry out titrations with carbonates in a warm solution. It is also claimed to be suitable for the titration of organic acids. The indicator is made by extracting the dried red leaves of the plant with hot alcohol and neutralising the faintly acid extract very carefully with decinormal caustic soda solution. A few drops of the resultant deep red solution which possesses a green fluorescence is sufficient for a titration.

Pan-American Conference on Standardisation.—It is proposed to hold a Pan-American Conference on Standardisation at Washington next year, under the ægis of the Department of Commerce. The South American Governments are to be invited to participate, and presumably the governing idea will be to endeavour to obtain the adherence of the various American Governments to United States standards.

Cinchona Products in Japan.—The Hoshi Pharmaceutical Co., of Tokio, has decided to increase its capital by 30,000,000 yen to 50,000,000 yen by amalgamating with the recently formed Kyodo Pharmaceutical Co. The increased capital will be used to build a new plant near Tokio, where the company intends to manufacture cinchona alkaloids on a larger scale than at present.

Calcium Carbide in Algeria.—The consumption of calcium carbide in Algeria, which imports all of its needs for this product, is considerable, especially in outlying districts where electric current is not available, states an American Consular Report. Imports in 1913 amounted to 4,821 metric tons. In 1919, only 1,659 metric tons were received. By 1921 imports returned to normal, reaching 3,134 metric tons, and in 1922, 4,025 metric tons, were imported.

Industrial Research in China.—The Peking Technical College has organised an Institute of Industrial Research. The institute's work is that of collecting and classifying products, both raw and manufactured, from all over China, and investigating and comparing the nature and quality of material with a view to devising means for improvement or to extending its use. Collecting is being carried out by sending out circulars and publishing advertisements requesting samples and special information.

Mineral Production of South Africa.—The mineral output of South Africa last year was valued at £38,394,376., made up of: Gold, £32,189,587.; silver, £171,324.; diamonds, £2,266,631.; coal, £3,467,412.; copper ore and concentrates, £37,036.; metallic tin and tin concentrates, £59,393.; and other base minerals, £202,993. Compared with 1921 this shows a decrease of £12,871,125, of which gold alone contributed £10,575,560. Coal sales were 9,725,479 tons, against 11,389,015 tons; copper, 705 tons, against 158 tons; and tin, 612 tons, against 1,431 tons. Corundum also showed a considerable increase, but the output of asbestos declined some £20,000. in value.

Imports of Dyestuffs into British Malaya.—Statistics of the values of imports of dyestuffs into British Malaya, showing countries of origin, during 1921, 1922, and the first four months of 1923, show that, although the market for aniline dyes in British Malaya is not an important one, the figures are noteworthy as showing from what sources such supplies as are required are forthcoming.

	1921.	1922.	1923 (4 months).
United Kingdom	£398	£454	£243
British Possessions	770	697	6
Continent of Europe	7,771	4,597	6,044
U.S.A.	20	nil	nil
Japan	nil	9	nil
Other Countries	1,735	708	181
Total	£10,694	£6,465	£6,474

Trade of Principal Countries.—The latest accounts relating to the trade and commerce of certain foreign countries and British Possessions, compiled by the Board of Trade, contain the following summary table, showing the total imports and exports of merchandise of the principal countries for which the particulars can be given during the periods of the three months ended March, 1922 and 1923.

Three Months ended March.	IMPORTS. Thousand £ (000's omitted).		EXPORTS (Domestic). Thousand £ (000's omitted).	
	1922.	1923.	1922.	1923.
Finland	19,534	35,151	18,208	19,996

BRITISH OVERSEAS CHEMICAL TRADE.

JULY IMPORTS AND EXPORTS.

In consequence of the dockers' strike there is a considerable falling off in the imports and exports of chemical and allied products during July, as compared with the previous month. Imports of chemicals, drugs, dyes, etc., comprised under Group N in Class III. of the Board of Trade returns, amounted to £796,366. in July, against £933,234. in June, and £831,976. in July, 1922. The value of British exports of these products amounted to £1,739,561 in July, compared with £2,385,072. in June and £1,444,643. in July of last year. In the table below are given the quantity figures of imports and exports for July and June.

IMPORTS—Increases on June Quantities.

		1923. July.	1923. June.
Borax	cwts.	7,450	2,610
Calcium carbide	,,	37,159	28,355
Cream of tartar	,,	4,588	2,064
Dyeing extracts	,,	8,533	8,070
Glycerine, crude and distilled	,,	2,209	362
Indigo, natural	,,	30	12
Petroleum, crude mineral	galls.	30,075,435	25,589,804
Potassium compounds (except nitrate)	cwts.	147,465	125,202
Potassium nitrate	,,	15,541	1,049
Pyrites, iron	tons	41,153	11,743
Sodium nitrate	cwts.	40,889	20,294
White lead	,,	8,453	7,427

Decreases on June Quantities.

Acetic acid	tons	752	987
Barytes, ground	cwts.	39,808	52,148
Bleaching materials	,,	1,608	4,981
Boron minerals	tons	375	1,824
Gums and resins (except rosin)	cwts.	23,963	30,690
Manganese ore	tons	37,296	39,467
Mercury	lb.	114,092	150,899
Nickel oxide	cwts.	1,860	3,614
Paraffin wax	,,	67,713	73,515
Phosphate of lime	tons	18,696	23,731
Rosin	cwts.	76,770	118,413
Sulphur	tons	715	17,670
Tanning extracts	cwts.	85,636	92,129
Tartaric acid	,,	2,680	4,616
Turpentine	,,	32,139	35,346
Zinc oxide	tons	484	811

EXPORTS—Increases on June Quantities.

Carbolic acid	cwts.	9,648	8,123
Dyestuffs, coal-tar	cwts.	15,023	9,191
Naphthalene	,,	19,856	19,303
Paraffin wax	,,	10,732	9,990
Salt (other than table)	tons	33,169	24,601
Sodium sulphate	cwts.	212,546	151,884
Tar, coal	tons	358	256

Decreases on June Quantities.

Ammonium chloride	tons	176	337
Ammonium sulphate	,,	20,586	24,065
Barytes, ground	cwts.	14,167	20,023
Benzol and toluol	galls.	67,763	247,393
Bleaching powder	cwts.	6,750	12,443

Cement	tons	54,924	57,629
Copper sulphate	,,	1,290	3,282
Disinfectants, insecticides, etc.	cwts.	23,634	31,488
Glue and size	,,	10,133	15,222
Glycerine, distilled	,,	3,986	5,815
Naphtha, coal-tar	galls.	9,281	39,020
Pitch, coal-tar	tons	4,542	18,499
Potassium chromate, and bichromate	cwts.	1,530	3,451
Potassium compounds (except chromate and bichromate)	,,	2,128	4,557
Soaps (total)	,,	90,972	111,844
Sodium carbonate	,,	414,608	564,615
Sulphuric acid	,,	1,961	2,779
Tar oil, creosote, etc.	galls.	2,029,275	8,577,741
Tartaric acid	cwts.	648	1,086
White lead	,,	15,811	18,775
Zinc oxide	tons	243	258

OUR BOOKSHELF.

Les Metaux Precieux (The Precious Metals). By Jean Voisin; 1922. Paris: Librairie J.-B. Baillierè et Fils, 19, Rue Hautefeuille. Pages, 264; paper backs; price, 25 francs (bound, 35 francs).

The work is one of the series on industrial chemistry published under the direction of M. Matignon, professor at the College de France, and with the patronage of the Union des Industries Chimiques de France and of the Société de Chimie Industrielle. The subject is treated from the triple standpoint of the properties of the precious metals, their industrial application and their economic rôle, and the metals dealt with are gold, silver, platinum, iridium, palladium, ruthenium, osmium and rhodium. Metallurgical and assaying problems come in naturally for detailed treatment, and it is probably from this and the economic standpoint that the book will be best received by the technical man. The sections on the industrial application of the metals such as for example those dealing with the manufacture of platinum apparatus and the use of platinum in catalysis are meant more for the general reader than the chemist. Still the work is primarily intended for the public and achieves its object creditably.

Betriebseinrichtigungen der Textilveredelung (Factory Building Design and Construction in the Textile Finishing Industry). By Dr. P. Heermann and Ing. G. Durst. 1922; Second Edition. Berlin: Verlag von Julius Springer; bound, 162 pages; price, 6s. 3d.

An excellent practical little volume, which although dealing specifically with the design and lay-out of plant for the dyeing, bleaching and finishing trades contains a volume of valuable information of quite general utility. Constructional details such as the use of steel, concrete and wood are dealt with and points such as the most suitable type and position of doors, windows, ventilators, etc., are discussed. Engineering questions such as the steam generating plant, steam piping, water piping, power transmission, lighting and fire prevention methods are reviewed, and the purification of the water supply and the disposal of waste effluents are the points finally dealt with. The work, which is excellently produced, contains 91 illustrations.

Elektrische Behandlung von Gasen (The Electrical Treatment of Gases). By Henri Silbermann; 1922. Leipzig: Verlagsbuchhandlung: Dr. Max Jänecke; paper backs; 348 pages; price, 8s. 6d.

Although principally a collection of patent specifications the book is of undoubted value. The first portion deals with the activation of oxygen-containing gases and more particularly with the preparation of ozone. The second and in our opinion most important section is devoted to the electrical precipitation of dust from gases and to the dispersal of mists. The third and last section deals with the effect of the electric current and the electric discharge upon mixtures of gases and deals with the synthesis of nitrogen oxides, ammonia, cyanogen, etc. The work is profusely illustrated, mainly with line diagrams as given in the patent specifications. Very little criticism as to the merits or demerits of the various types of process or plant is given, but as a compilation of the important relevant patents the volume should command a good number of interested readers.

Die Entwicklung der Chemischen Technik bis zu dem Anfangen der Grossindustrie. By Dr. Gustav Fester. 1923. Berlin: Verlag von Julius Springer; pp. 226; paper backs; price, 6s. 3d.; bound: price, 7s. 6d.

The title translated is "The Development of Chemical Technology up to the Foundation of the Heavy Chemical Industry." The work is based upon a course of lectures given by the author to the students at Frankfurt University in 1919 and is divided into three parts, the chemical technology of the ancients and of the Middle Ages, the chemical technology of the later Middle Ages to the beginning of the seventeenth century, and chemical technology from the seventeenth to the commencement of the nineteenth century. Both to the student of chemical history as such and to the student of modern technology the work should be of considerable interest. From the scientific standpoint the history of chemistry is well provided for in the literature, but a work dealing entirely with the technical aspect of such history has long been wanted. The total absence of illustrations is however to be regretted.

SOUTH WALES NOTES.

[Specially Contributed.]

There is a better demand for tinplates, some important orders having been secured for the Far Eastern markets. Production is well maintained, all the factories having restarted this week. There are numerous inquiries from Japan, and it is likely that much of this business will be placed in South Wales. Full employment is being given at the coke ovens and by-product plants. Cokes are in strong demand and prices remain very firm, Continental requirements having become much more pressing, not only for immediate delivery, but also for dispatch over the next four months. The patent fuel trade keeps moderately quiet. Small coals are plentiful, and slightly lower in price, but although there are good supplies of American pitch, the price is such that consumers of briquettes are not likely to obtain reductions at present. There are indications however, that pitch prices will be reduced in a few weeks' time. Lead workers have more employment, but copper workers are not fully employed, and there seems no likelihood of improved business. The nickel industry is fairly well off for orders and the by-products are selling well.

Included in the week's imports were 9,824 tons concentrates from Port Pirie, 200cwt. magnesite from Hamburg, 6,572 tons pitch from Pensacola, 38 tons lead ore from Toronto, 2 tons copper precipitate from Havre, 2,000 tons concentrates from Dunkirk, 2,019 tons zinc concentrates from Port Pirie to Swansea; 1,249 tons precipitate of copper from Huelva to Port Talbot; 426cwts. phosphorus from Montreal to Cardiff; and 3,300 tons of crude sulphur from Porto Empedocle to Newport.

NEW COMPANIES.

Stainless and Non-Corrosive Metals, Ltd.—Capital £5,000. Purchase consideration £1,000. Office: 14, Weaman Street, Birmingham.

Charles Morrison Compositions Company, Ltd.—Private company. Capital £5,000. Lead, paint, colour, and varnish manufacturers, etc. Office: 12, Great St. Helens, London, E.C. 3.

Hibbs and Wishart, Ltd.—Private company. Capital £5,000. Agents, manufacturers, merchants, shippers of oils, soap, and chemicals, etc. Office: 10, Exchange Buildings, St. Mary's Gate, Manchester.

Hydra Lime Products, Ltd.—Private company. Capital £3,000. (2,700 ordinary shares of £1. and 6,000 deferred ordinary shares of 1s.). Office: 25, Cross Street, Manchester.

John Musgrave, Ltd.—Private company. Capital £2,000. Dyers and finishers, etc Office: Grove Dyeworks, Meanwood Road, Leeds

Jopson, Bardsley and Jopson, Ltd.—Private company. Capital £75,000. (15,000 preference). Dyers and finishers. Office: Carr Dye Works, Nelson, Lancs.

National Carbonised Fuel and By-Products Syndicate, Ltd.—Private company. Capital £12,500. Office: Fitzalan House, 13, Arundel Street, London, W.C. 2.

Robinson, Nelson and Co., Ltd.—Private company. Capital £5,000., £1. shares (1,800 ordinary and 3,200 preference). Dealers in laboratory apparatus and furnishings. Office: 378, City Road, Manchester.

Thames Lubricants, Ltd.—Private company. Capital £1,000. Producers, refiners, storers, etc., of chemicals and oils, etc. Office: 11, Victoria Street, Westminster, London, S.W.

British Cast-iron Research.—The British Cast Iron Research Association in the monthly bulletin (June, 1923) of research in hand, states that important arrangements are being made for carrying out a thorough investigation upon foundry sands. The work will probably be done at the Birmingham University and in one of the large foundries. The Bureau of the Association are issuing a complete bibliography of sand literature. A Joint Research with the Electrical Research Association is being arranged to carry out investigations on sea-water resisting cast iron. It is estimated that the experimental work will occupy about two years and will be carried out at the coast and in tidal rivers. The Association consider that the time has arrived when a standard specification for Grey Iron Castings should be drawn up, and steps have been taken to have this carried out in conjunction with the B.E.S.A.

FERTILISER NEWS.

Nitrate of Soda.—The nitrate producers continue to maintain prices at the high levels fixed by the Committee in May last, and there has even been talk of a further increase during the current season. It is reported, however, that the Chilean Government has strongly opposed this step, the excuse for which was the unfavourable exchange conditions. As regards this difficulty, a draft Bill was prepared by the Minister of Finance in the late Government, which went out of office in June last, but it is learned that no further action in respect of controlling foreign exchange operations is contemplated. So far as the nitrate industry is concerned, the policy of the Chilean Government is to have nitrate selling prices as low as possible in order to encourage consumption, for the revenue of the country is mainly derived from the export duty on the fertiliser. It is hardly to be expected, however, that prices will be lower at present, although much dissatisfaction is being expressed by America, which is Chile's largest customer for nitrate. The demand in that country is much quieter, but will probably become stronger as the application season draws nearer, and cotton growers receive payment for the present crop. Strong efforts are being made in the States to obtain reductions in nitrate quotations, and many arguments savouring a little of "bluff" are being brought forward. To voice loud complaints that the sellers, and not the buyers, of a commodity fix the prices seems a little illogical, for an industry which fixed its selling prices on the advice of the consumer would not last very long. To threaten a monopoly like the Chilean nitrate industry with unlimited production of atmospheric nitrogen products, and, at the same time, make no move towards the development of such processes, is equally futile. So long as competition is restricted mainly to by-product sulphate of ammonia there will always be sufficient demand for nitrate to enable the Producers' Association to maintain prices at an unduly high level. The most effective attempts to combat the Chilean trust are, after all, being made in this country by Messrs. Synthetic Ammonia and Nitrates, Ltd., at Billingham, and Messrs. The British Cyanides Company, Ltd., at Oldbury.

Sulphate of Ammonia.—The very favourable position occupied by the British producers of sulphate of ammonia is strikingly emphasised in the recently published figures of the July exports. In spite of the dockers' strike, shipments have been maintained at 20,586 tons, compared with 24,065 tons for the preceding month, and 7,387 tons for July of last year. Aided by the position in America, by the political situation in Europe, and not the least by the policy of producing a really high-grade material, the world-demand for the British product continues strong. The most important facts to be noted in connection with the July exports are the entire disappearance of France from the list of customers and the increasing demand from Japan. The latter country indeed, leads the way by taking 8,272 tons out of the 20,586 tons exported last month, making a total of 28,664 tons since January 1 of this year. Considering that at this time last year, the seven months' figure reached only 51 tons, it is clear that the lack of American material of equal quality and price, and the absorption of heavy stocks of previously imported sulphate, have disposed the market in favour of the British product. Our next best customer on the month, Spain, took rather less than in June, although much exceeding the figure for July of last year. During last month 4,915 tons were dispatched, against 7,955 tons in the previous month, and 1,826 tons in the corresponding month of 1922. This brings the total for the current year, to date, to 44,611 tons. The British West Indies were lower at 808 tons in July, compared with 1,114 tons in June, but here, again, advantage has been taken of the general situation to sell 6,672 tons since the beginning of the year, against 2,778 tons last year. The imports of British sulphate into the Dutch East Indies have been considerably decreased, 766 tons being shipped in July, compared with 3,838 tons in June; nevertheless, the seven months' figure shows a 50-per-cent. increase on last year. In Italy, despite the large stocks of German reparation material and the energetic competition of other nitrogenous fertilisers, shipments of British sulphate of ammonia were maintained at 444 tons, compared with 360 tons in June, and 106 tons in July, 1922. Countries not specified accounted for 5,381 tons, a shade less than the June figure, but a considerable advance on the total for the same month of last year, 1,798 tons. In all, 144,146 tons of sulphate, having a value of £2,424,245., were exported during the seven months January 1 to July 31, against 74,099 tons worth £1,201,667., in 1922.

Other Fertilisers.—Basic slag during July was a diminishing trade, imports and exports sharing in the reduction. Exports during the month fell from 1,265 tons in June to 353 tons in July, while imports were lower at 4,366 tons last month, compared with 5,752 tons in the preceding month. The trade in superphosphate is of a better nature, 1,495 tons being exported in July, against 1,308 tons in June, and 318 tons in July last year. The total exports since January 1 amount to 7,864, just double the quantity for the corresponding period of 1922. Exports of compound fertilisers are well maintained at 3,604 tons, bringing the seven months' total up to 33,223 tons, compared with 18,258 tons last year. No imports of raw guano were made during July. In regard to other raw materials for the fertiliser industry, imports of phosphate rock declined from 23,731 tons in June to 18,696 tons in July, compared with 32,944 tons in July, 1922. Receipts for the period up to July 31 are lower than for last year by about 34,000 tons. It is interesting to note in connection with the development of the Moroccan phosphate deposits that the broad gauge railway leading from the deposits in the Oued Zen district to the silo built on the big breakwater at Casablanca will be open to traffic at the beginning of September. It is expected that the exports this year will reach 200,000 tons, while it is confidently anticipated that from 1924 onwards the annual export will be about 500,000 tons. Sulphur imports experienced a considerable drop to 715 tons in July, compared with 17,670 tons in June. Nevertheless, on the basis of seven months' shipments, the quantity imported is between two and three times the total for the same period of last year. Pyrites, on the other hand, were an improved trade at 41,153 tons, against 11,743 tons in June, and 35,961 tons in July, 1922. At the same time, the total imports for the year up to date indicate a slight falling off in comparison with last year.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

No week is quite like the week that has passed, and though no material improvement can be expected until autumn it is a fact that the position is slightly better temporarily. There is now some prospect of an increase of production in the hematite pig-iron trade, the expectation being that a furnace may be relighted at Cleator Moor which is one of those that consume the local coke, and in that event it may well be the case that the demand for coke may be somewhat larger than can be comfortably satisfied. One of the satisfactory features of an otherwise disappointing situation is that such furnaces as have been damped down have been those that are not ordinarily big users of other than East Coast coke, the result being of course that all the ovens with the exception of the Whitehaven ovens, which are still idle, have been kept in full operation whenever adequate supplies of small coal have been available. It is evident that the question of having at command all the coal that is wanted at times when the requirements of coke by iron smelters in the district are as great as can be met is one which sooner or later must engage serious attention. The time is not far distant, it may be stated, when some of the existing coking plants will have to be enlarged. And when that takes place it is easy to see that the new ovens will be those of the American type. One of the local collieries has already received a report by representatives who paid a visit to plants in America on the developments that are needed in Cumberland, and it seems certain that extensions will be made directly it is ascertained that the collieries themselves can be so developed that the increased output may be forthcoming. At the present time the coal production falls considerably short of what is aimed at, even after taking into consideration the stoppage at Whitehaven. As to coke itself the greater part of the production is being absorbed by the furnaces that are blowing at Workington and a little by a furnace or two in North Lancashire, the price quoted being 29s. to 33s. per ton according to carbon content. There is a strong Continental inquiry at 34s. to 40s. per ton, f.o.b., and the shipments to Hamburg and Bremen have risen almost to 2,000 tons per week. East Coast coke supplies this week are again 8,100 tons. Residuals are fairly active. All the tar is being taken by the chemical works. Sulphate of ammonia is moving away satisfactorily.

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS IN JULY.

THE following returns, which are taken from the import statistics of the United Kingdom, give the amount and value of chemicals and allied products imported during the month of July, 1923, compared with 1921 and 1922. As from April 1, 1923, the import trade of the Irish Free State is excluded from the returns.

(To be concluded.)

REPORTS OF COMPANIES.

Centrifugal Separators, Ltd.

The third annual general meeting was held in London on Friday, August 10, Commander Sir Arthur Trevor Dawson presiding.

The Chairman, in moving the adoption of the report and accounts, said that a year ago he had stated that although the number of machines actually sold was not large they had quite a considerable amount of business in prospect. If he were to use these same words again he believed he would be summing up the position at this date quite correctly, and if he spoke with hope last year he certainly felt that he could do so now—probably not quite as regarded immediate results, but, viewing the prospect generally, he was advised that there were distinct indications of an improvement, given a maintained improvement in other trades. One satisfactory feature was that in industries regularly using the separators the machines were giving satisfaction. A testimonial had come to hand only this week from a very well-known firm who had had two of the machines working for two years. With regard to the subsidiary company referred to in the report, it had been formed to place upon the market an improved type of separator, and all the indications pointed to their being able to do a remunerative business in that direction. It would not compete with, but might even help the sale of, the Gee Separator. The China Clay Company, in which they were large shareholders, had since last year been manufacturing and selling china clay of a high quality. The clay which had been manufactured had been made by the Gee machines, and it was of a quality equal, if not superior, to the best china clay upon the market.

The report and accounts were unanimously adopted.

DIVIDENDS.

Bradford Dyers' Association.—Interim dividend for the year to December 31 next on the ordinary shares at the rate of 1s. per share, subject to income tax. At this time last year the interim distribution was at the same rate.

Goodlass, Wall and Co., Ltd.—Profit for year to June 30 £53,386., plus £13,066. brought in. Balance of formation expenses, £12,198, written off; dividend on ordinary of 12½ per cent., less tax; £1,794. written off vehicles, and balance, less corporation profits tax and management commission, carried forward.

Eastman Kodak Company of New Jersey.—Quarterly dividends of 1¾ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of $1.25. per share upon the outstanding common stock (the same as a year ago).

National Lead Company.—A quarterly dividend of 2 per cent. has been declared on common stock.

British Oil and Cake Mills, Ltd.—Interim dividend on ordinary of 5 per cent. (less income tax) for current year.

THIRTY-FIVE YEARS AGO.

(From the "Chemical Trade Journal," August 18, 1888.)

The Chemical Trade in Italy.—Milan is the centre of the Italian chemical industry, a branch which has of late years made very considerable progress. There are now in Milan two works manufacturing sulphuric, nitric, and hydrochloric acid, crude and chemically pure, as well as salammoniac and liquid ammonia; while three works at Milan and one at Brescia turn out citrate of magnesia to a total value of about £20,000. per annum. A camphor refinery, the first in Italy, was established last year. Another chemical works refines annually some 700 tons of glycerine, purchasing for this purpose a large proportion of crude glycerine from the Italian stearine works. There is one large quinine manufactory in Milan, which also makes iodide of potassium and other iodides. There is also another works in Milan which makes a speciality of iodides, bromides, bismuth preparations, salicylates, etc., besides producing various pharmaceutical articles. In Pavia a large manufactory of antiseptic surgical appliances exists, which have a large sale all over Italy. Tartar materials are treated in seven different manufactories, while in Milan there are no less than fifty manufacturers of common and toilet soaps, some of whom carry on a considerable wholesale and even an export trade. Vegetable-oil refineries are found in large numbers, no less than two hundred such establishments existing in the province of Lombardy alone.—*Oil, Paint, and Drug Reporter.*

GAZETTE NEWS.

MORTGAGES AND CHARGES.

Glamorgan Patent Fuel, Ltd., Caerphilly.—Registered July 23, £4,000. deb., to Branch Nominees, Ltd., 15, Bishopsgate, London, E.C.

Hewett and Reynolds, Ltd., London, N.W., dyers.—Registered July 26, mort., to Barclays Bank, Ltd., securing all moneys due or to become due to the bank.

Industrial Silica, Ltd., London, W.C.—Registered July 21, £15,000. 1st debs. (secured by deed of conveyance and Trust Deed, both dated July 9, 1923).

Klensit Soap Company, Ltd., Ashton-under-Lyne.—Registered July 28, £504. mort., to Halifax Permanent Benefit Building Society.

Redaluma Paint Company, Ltd., London, E.C.—Registered June 30, £600. mort., to A. H. Relf, Torry Glen, Woodford.

Shankland (G. A.), Ltd., Eynsham, chemical manufacturers.—Registered July 19, £18,000. debs.

Travancore Minerals Company, Ltd.—Registered July 27, Trust Deed securing £35,000. debenture stock, to London City and Midland Executor and Trustee Company, Ltd., 5, Threadneedle Street, London, E.C.

Union Match Company, Ltd., London, E.C.—Registered July 27, charge, to Union Allumettière Société Anonyme, 97 and 99, Rue des Etangs Noirs, Brussels, securing all moneys due or to become due to chargees.

SATISFACTIONS.

Gilbert and Knowles, Ltd., London, E.C., chemical merchants.—Satisfaction registered July 30, £300., balance of amount registered September 1, 1921.

Hudson (R. S.), Ltd., Liverpool, soap makers. — Satisfaction registered July 27, £400,000., balance of amount registered July 28, 1908.

Klensit Soap Company, Ltd., Ashton-under-Lyne.—Satisfaction registered July 28, £500., registered February 19, 1920.

LIMITED COMPANIES. — Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions; Orders; and Official and Other Notices.

Kleenit Soap and Chemical Company, Ltd.—Resolved July 9, confirmed July 24: That the company be voluntarily wound up. P. Stapleton, 27, Waterdale, Doncaster, liquidator.

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

Blunt, W. H., and Son, 70, Snow Hill, Birmingham; chemists; £12. 8s. 7d. June 6.

British Colloidal Products Company, 2, Cooke Street, Hulme; dyestuff manufacturers; £11. 1s. 4d. June 27.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

South Africa.

The Municipal Council of Johannesburg are calling for tenders, to be presented by September 18, 1923, for the supply of white lead, oils, paints, varnishes, etc. (Contract No. 120.) (Ref. No. 11887/E.C./C.C./2.)

Norway.

A firm of commission agents in Christiania desires to secure the representation for Norway of British exporters of feeding stuffs, and raw materials used in the manufacture of soap, margarine, etc. (Reference No. 174.)

A commission agent in Christiania desires to secure the representation for Norway of British exporters of coal-tar pitch, etc. (Reference No. 176.)

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Application of Chlorine. J. W. van Meter, San Francisco, California, U.S.A. British Patent, **199,052**, of 1921.

An apparatus for use in the application of chlorine and chlorine water in water purification, the preparation of dyes, bleaches, and laundry preparations and other purposes comprises an upper chamber adapted to receive a continuous supply of liquid, which is then fed to a lower transparent vessel in which is disposed a second transparent vessel, open at the bottom, graduated and having a bleeder port for the passage of chlorine to the outer vessel. In the production of chlorine water, water is continuously delivered to the upper chamber, while if dry chlorine is required, kerosene may be used. Figs. 3 and 4 show sections of the

FIG 3.

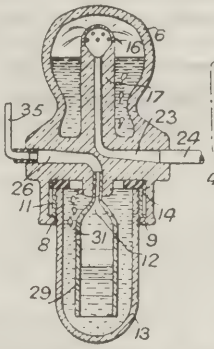

FIG 4.

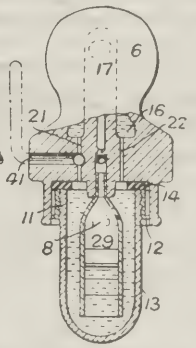


apparatus at right angles to each other. Liquid is sprayed into the chamber 16 in a hollow casting 6 by means of a hose 24 fitted to a passage 23 passing through the tubular member 17. The liquid is fed by the tubes 21, 22 to a lower transparent vessel 13 screwed into a collar 11 with flange 12 against a rubber gasket 14, the collar being held in position by lugs 8, 9. A supply tube 35 delivers chlorine to a passage 26 and thence to a transparent funnel-shaped graduated vessel 29 with a bleeder port 31. The liquid and chlorine pass out of the apparatus together by the tube 41. In operation, the apparatus is first filled with liquid the level of which is observed in a sight bulb provided in the chlorine supply-tube 35. The chlorine valve is then opened and the depression of the liquid level observed measures the pressure of chlorine delivery, from which the rate of flow of chlorine may be deduced, knowing the size of the aperture 31.

Pyrazolone Derivative. O. Y. Imray, London. (Soc. of Chemical Industry in Basle, Basle, Switzerland.) British Patent, **198,829**, of 1922.

1 - (2¹-Methyl-3¹-sulpho-5¹-isopropyl-) - phenyl-3-methyl-5-pyrazolone is prepared by condensing the hydrazine from 2-aminocymene-6-sulphonic acid with ethyl acetoacetate. An example is given in which diazotised aminocymene sulphonic acid is reduced with sulphite and the hydrazine then condensed with ethyl acetoacetate. Monoazodyes which dye wool in yellow shades similar to those of tartrazine but faster to light are obtained by coupling the above described pyrazolone derivative with diazo compounds of the benzene or naphthalene series; in an example diazo-benzene is used.

Utilising Paper Waste. A. L. Burlin, Manchester. British Patent, **198,789**, of 1922.

Paper waste is de-inked and de-colourised by treatment for about ten minutes with soda ash at a temperature of 35° C., after which oxalic acid is added and the mass again agitated, the period of treatment usually ranging between fifteen minutes and one hour. Alternatively the soda ash and oxalic acid may be added together. The mass is washed with soda ash and oxalic acid. The pulped waste is agitated and may then be further treated with a small quantity of a bleaching substance. It is stated that 8lb. of soda ash and 2lb. of oxalic acid suffice for the treatment of 5cwt. of ordinary newsprint waste.

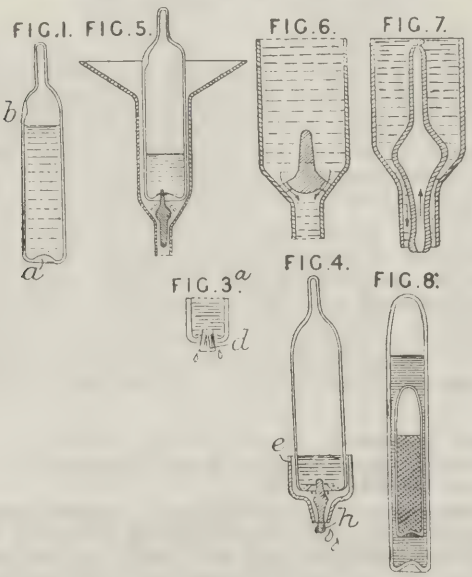
Recovering Coal from Sludge. T. Steen, Berlin. British Patent, **198,529**, of 1922.

The sludge resulting from washing coal is run on to a vacuum draining floor and is dried thereon. The stream of sludge may be divided, the fine coal being led to the floor with a minimum amount of water and the remainder of the sludge containing the coal dust being led to a settling tank or elsewhere for separate treatment, for example for reduction of the ash content. The thickened sludge from the settling tank, or the portion of the sludge which has been treated separately may be led to the draining floor with the main stream, or it may be dried separately. If the sludge contains much foreign matter, the fine coal may be completely separated, for example by means of a rake, and led to the draining floor in a stream of water, the residual sludge being concentrated separately and re-united with the fine coal before or after the latter reaches the draining floor. The separated fine coal may be transported to a storage tower and the sludge dried on the draining floor until it crumbles. Circular or annular drying troughs may be used. To remove salts such as magnesium chloride, fresh water is added to the partly-dried sludge on the floor, so as to wash out the residual water which contains dissolved salts.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Making Standard Solutions. F. W. Horst, Neckargemünd, Germany. British Patent, **198,993.** Convention date, June 6, 1922.

Reagents for making standard solutions are weighed and enclosed in airtight containers, each container containing a quantity corresponding with a particular volume, say 1



litre, of the solution to be prepared. The reagents may be mixed with a substance facilitating the weighing or having preservative properties such as a salt or colloid, and the weighing may be effected in an inert atmosphere. An excess of the substance may be first taken, the excess being removed by suction until the scale balances. The containers may be glass flasks having a weak portion, preferably in a recess adapted to be broken when the reagent is to be used. Such weakened part may be at the bottom *a*, Fig. 1, and a second weakened part *b* may be provided for more easily emptying the container. The weakened part may be broken by a tool or mandrel and the opening may be plugged with a material such as glass wool *d*, Fig. 3a, to retain fragments of glass. The mandrel may be arranged in a funnel *e*, Fig. 4, and may have an enlarged end *h* for preventing it falling out. The mandrel may be ribbed to allow the liquid to flow past it more easily, and may be tubular, Fig. 7, to allow of air entering the container as the liquid leaves. The mandrel may be attached to the funnel, Fig. 6, channels being provided for the liquid to pass through. The funnel may be shaped so as to guide the container, Fig. 5, the container being simply dropped into place. Several containers may be arranged one within another, having the weakened parts in line, Fig. 8, so that they may be fractured simultaneously. The reagents mentioned are permanganate, phthalic acid, aniline hydrochloride, betain hydrochloride, iodates for iodine determinations, sulphanilic acid for nitrite determinations, diazotised aromatic amines, nitraniline, dyes, and pharmaceutical preparations.

Catalytic Materials. C. Urfer, Geneva. British Patent, **199,030.** Convention date, June 12, 1922.

Catalytic materials, for use especially in the synthesis of ammonia, are obtained by heating a reducing metal with the halide of a metal capable of forming a nitride when heated in nitrogen and whose nitride decomposes when heated with hydrogen, and cooling the reaction mass *in vacuo*, nitrogen or hydrogen. The reducing metals mentioned are sodium, potassium and calcium, whilst the metals whose halides are employed comprise cerium, lithium, calcium, strontium, barium, lanthanum, thorium, glucinum, zirconium, vanadium and molybdenum. The product consists of the nitride-forming metal or its nitride in the pulverulent state mixed with the halogen compound of the reducing metal which functions as an inert support. The halide is generally the chloride, but bromides, iodides and fluorides may also be used; fluorides are employed when the chlorides are deliquescent. According to the example, equimolecular quantities of lithium chloride and sodium or potassium are heated *in vacuo* or in nitrogen.

Ammonia Synthesis. C. Urfer, Geneva. British Patent, **199,032.** Convention date, June 12, 1922

A catalytic material for the synthesis of ammonia comprises a mixture of (1) the nitride or amide of a metal, such as the alkaline earth metals and lithium, which gives a nitride or amide when heated with nitrogen or ammonia and whose nitride or amide is decomposed by heating in hydrogen; (2) an inert oxide, such as magnesia, alumina and lime, and (3) a metal, such as lead, cadmium, bismuth, antimony, commercial zinc (which contains bismuth, cadmium and lead as impurity), gold, copper and silver, which accelerates the decomposition in hydrogen of the nitride or amide. With the exception of zinc, all the meals mentioned under (3) above are prepared by heating the oxides in hydrogen, preferably in the presence of the inert oxide to prevent fusion. Ammonia is obtained by passing either a mixture of nitrogen and hydrogen or nitrogen and hydrogen alternatively over the catalytic material at a temperature less than 600° C. and at atmospheric pressure.

MARKET REPORTS.

LONDON "OPEN MARKET" REPORT. Wednesday.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals. — Since the resumption of business there has been but little activity in this market, and it seems that the present dull period is likely to continue through August. Prices, however, show no sign of any further material move in buyers' favour. **Acetic Acid,** 80% technical, £47. to £48.; 80% pure, £50.; 98% glacial, £60. in casks and £75. in glass demijohns, ex wharf London; stocks are reported limited on spot, with prices fully maintained. **Acetone,** British Government specification, about £130. to £135. per ton, nominal; there are no stocks of any size to offer on spot, while inquiry is as good as ever; prices are

likely to go still higher, owing to a world shortage. **Arsenic,** Cornish, white powdered, about £72. to £73. per ton, for spot parcels; inquiry for these goods is still very small. **Alum,** lump, £10. to £10. 10s. per ton, in casks; dealers are offering imported material at about these figures; demand small. **Anhydrous Ammonia,** 99.95%, 1s. 5d. per lb.; the market has been quiet of late; prices quoted unchanged. **Barium Chloride,** 98—100%, £15. to £15. 5s. per ton, on spot; dealers find business still very slow. **Bleaching Powder,** 35—37%, £10. to £10. 10s. per ton; importers are offering at these rates for shipment, but do not seem to be selling much. **Borax,** commercial, granulated £26. 10s., crystals £27., powdered £28., extra fine £29.; B.P., crystals £31., powdered £32., extra fine £33. per ton, for home trade only, in 2cwt. bags (free), carriage paid to destination. British makers quoting at these unchanged rates for home trade only; their prices for export vary as to destination; dealers are offering for home consumption under similar conditions to makers at: Granulated £25. 10s., and powdered £27. per ton. **Borax Glass,** lump, £74.; powdered, £75. per ton, in tin-lined cases; British makers' prices, to home trade only, are unchanged at these prices, packages free, carriage paid in the United Kingdom. **Boric Acid,** commercial, crystals £50., powdered £52.; B.P., crystals £56., powdered £60., extra fine £62. per ton, in free bags, carriage paid to destination; British makers' quotations, for home trade only, are unaltered at these rates; dealers are quoting some grades on spot at competitive rates. **Cream of Tartar,** 99—100%, 90s. to 92s. per cwt., less 2½%, in one-ton lots; this market keeps very steady at these prices, with a fair volume of business passing. **Citric Acid,** B.P., crystals, about 1s. 6½d. to 1s. 7d. per lb.; these are the quoted prices, but, owing to the weakness of the market, the actual selling prices are a matter of negotiation. **Epsom Salts,** commercial quality, about £5. per ton, in bags; business in dealers' hands is still very quiet. **Formaldehyde,** 40%, about £95. per ton; this market is still very quiet. **Glauber's Salt,** commercial quality, £3. 15s. to £4. per ton, in bags; dealers are doing hardly anything in this product; prices unchanged. **Lead Acetate,** brown, about £41. to £41. 10s.; white, about £42. per ton; spot lots are offering, with the demand poor. **Litharge,** pure flake, British, about £37. per ton; imported material is quoted at about £36. per ton, and is moving off slowly. **Lithopone,** 30% Continental red seal, £22. to £22. 10s. per ton; this market keeps very steady, with a fair volume of business passing through dealers' hands. **Ammonium Chloride,** grey galvanising, £30. 10s. to £31. per ton; any demands on spot are for small quantities; prices seem fairly steady. **Nickel Sulphate,** home trade, single and double salts, £38. per ton, delivered; export, single and double salts, £38. per ton, f.o.b.; British makers' prices stated. **Oxalic Acid,** about 6d. per lb.; the position, so far as dealers are concerned, remains very dull. **Carbonate of Potash,** 90—92%, about £27. 10s.; 96—98%, about £31. per ton; the market is steady at these values, but business is still slow and small. **Chlorate of Potash,** crystals and granulated, about 3d. per lb.; it would probably be difficult to book orders at this price. **Caustic Potash,** 88—92%, on spot, £32. to £32. 10s. per ton, in drums; dealers are offering at these prices, with occasional business about. **Permanganate of Potash,** commercial quality, about 9d. to 9½d. per lb.; the spot position keeps very steady at about these values, with some little business about. **Prussiate of Potash,** yellow, about 1s. 2d. to 1s. 2½d. per lb.; spot offers are being made at these rates, with a fair volume of business being done. **Sulphate of Potash,** 96%, £11. 10s. per ton, ex ship; this market shows no change. **Mercury,** about £10. 5s. to £10. 10s. per bottle of 75—76lb.; prices seem steady, with the market quiet. **Red Lead,** imported, about £36. per ton; importers are doing a limited business at about this rate. **Salammoniac,** dog-tooth crystals, £48. 10s. to £49.; medium, £43. to £43. 10s.; fine white crystals, £26. to £27. per ton; supplies are offering on spot at these rates, with business slow and small. **Saltcake,** ground and unground, home trade, about £4. 10s. per ton; export, about £5. 5s. to £5. 10s. per ton, f.o.b. **Acetate of Soda,** about £25. per ton; importers are quoting at about this price for forward delivery. **Soda Ash,** 58% light alkali, £7. 12s. 6d. per ton, in bags, carriage paid to destination; British makers selling for home trade only at this price; their prices for export vary according to destination. **Soda Crystals,** £5. 5s. per ton, in bags, carriage paid to destination; British makers quoting at about this price, for home trade only; dealers are offering at competitive prices. **Caustic Soda,** 70—72%, £18. 10s.; 76—77%, £20. 10s. per ton, in drums, ex wharf shipping port; dealers quoting at these unchanged prices, with not much inquiry about; British makers' prices, for home trade only, show no change at £19. to £21. 10s. per ton, in drums; their prices for export vary as to destination. **Bicarbonate of Soda,** £10. 10s. per ton, in bags; British makers' prices for home trade only quoted, in free bags, carriage paid. **Bichromate of Soda,** home trade, 4½d. per lb.; export, about 5d. per lb.; British makers selling at these levels. **Cyanide of Soda,** 98—100%, export, about 8½d. to 9d. per lb.; home trade, about 10½d. per lb.; British makers' quoted rates show no change. **Nitrate of Soda,** 96%, £13. 7s. 6d. per ton, f.o.r. Liverpool; the position shows no change on the week; market steady. **Nitrite of Soda,** 100%, about £26. 10s. per ton; prices quoted are unaltered. **Prussiate of Soda,** about 6½d. per lb.; dealers continue to compete very keenly for what little business there is about. **Hyposulphite of Soda,** pea crystals, about £14. 10s. per ton, in 1cwt. kegs; commercial quality, £10. per ton, in casks; dealers are doing a little business at about these prices. **Sodium Sulphide,** 60—62%, solid, £14.; ditto, broken, about £15. per ton; dealers are offering Continental material at about these levels, with little moving off; 60—65% concentrated, £15. per ton, in casks. **Sulphate of Copper,** about £26. per ton; Continental offerings are still very cheap; business is slow. **Tin Crystals,** 1s. 4s. per lb.; the market shows no change on the week. **White Lead,** imported, about £43. per ton; importers are selling in small quantities at about this price. **Zinc Oxide,** B.P., about £51.; white seal, about £43.; 99.5%, about £37. 10s. per ton, f.o.r. makers' works; British makers quoting at about these prices

Pharmaceutical Chemicals.—A continuance of slow business of very limited size is reported from most quarters in this market. Prices are being fairly well maintained, and this week there is no change of importance to comment upon. **Acetanilid,** crystals and powdered, 1s. 5d. per lb.; the market is not firm at this figure; business quiet. **Acetyl-Salicylic Acid,** B.P., 3s. to 3s. 1d. per lb.; spot parcels of good brands are offering at these prices, with the demand poor. **Benzoic Acid,** B.P., about 2s. 3d. to 2s. 6d. per lb., nominal; no inquiry on the market. **Diethylbarbituric Acid,** B.P. (barbitone), about 20s. to 21s. per lb.; at these rates the market keeps up very well, although there is little doing. **Salicylic Acid,** B.P., about 2s. 2d. to 2s. 3d. per lb.; the market keeps very steady, but business is rather slow. **Tannic Acid,** leviss, about 3s. 3d. per lb.; the spot position is steady at this rate, with business quiet. **Amidopyrin,** about 14s. to 14s. 6d. per lb.; the prices quoted govern a steady but quiet market. **Ammonium Bromide,** 7d. to 7½d. per lb.; spot supplies are still being freely offered, with nothing much moving off. **Benzonaphthol,** about 5s. per lb.; nominal; the market remains idle. **Benzaldehyde 03,** about 3s. per lb.; quoted rates on spot are unchanged; market dull. **Betanaphthol,** resublimed, about 1s. 10d. per lb.; the market remains rather dull, with quoted prices unaltered. **Calcium Lactate,** about 1s. 9d. per lb.; this market is much steadier after the recent big drop in values. **Chloral Hydrate,** duty paid, about 4s. per lb.; the spot position is well maintained at this rate, and some business has been done. **Creosote Carbonate,** about 8s. 6d. per lb.; this market remains quiet, with quoted values level on the week. **Creosote, B.P.,** about 2s. 2d. per lb.; this market is very steady, although there has not been much doing of late. **Guaiacol Carbonate,** about 8s. 3d. per lb., nominal; market still idle. **Hexamine,** about 3s. 10d. per lb.; there is no sign of any further break in the spot price of this product. **Hydroquinone,** about 3s. 6d. per lb.; the spot market keeps well up to this figure, although business has been rather slower. **Methyl Salicylate,** 2s. 5d. to 2s. 6d. per lb.; prices are quoted very steadily at these levels; business moderate. **Methyl Sulphonal,** about 15s. per lb.; the market shows but little life; prices quoted unchanged. **Paraformaldehyde,** 3s. 9d. to 4s. per lb.; this market is much steadier, and some little business has been done. **Paraldehyde,** about 1s. 5d. per lb.; the spot position is still rather unsteady, with not much business about. **Phenacetin,** about 6s. per lb.; this is the average price asked, but some large quantities might be offering at slightly less. **Phenazone,** about 7s. 6d. per lb.; last week's recovery is well maintained on spot. **Phenolphthalein,** 6s. 6d. to 6s. 9d. per lb.; the little offering is firm at these rates. **Piperazine,** 4s. 6d. per oz.; the spot offer from dealers is generally at about this rate for small quantities. **Potassium Bromide,**

crystals and granulated, 6½d. to 7d. per lb.; prices quoted by dealers holding spot material are varying very much, and competition for the little business about is very keen. **Potassium Permanganate,** B.P., 10d. to 10¼d. per lb.; the market keeps well up to these figures on spot, with business better. **Potassium Sulphoguaiacolate,** about 5s. 6d. per lb.; no interest being shown in dealers' spot offers at about this figure. **Salol,** 2s. 8d. to 2s. 9d. per lb.; nothing offered here below these rates. **Sodium Benzoate,** about 2s. 6d. per lb., nominal; market still lifeless. **Sodium Bromide,** crystals and granular, 7d. to 7½d. per lb.; on spot material seems very plentiful, and holders seem willing to cut their prices in order to effect sales. **Sodium Diethylbarbiturate,** about 19s. per lb.; on spot dealers are quoting this rate, with business limited. **Sodium Salicylate,** powder, about 2s. 5d.; crystals, about 2s. 9d.; flake, about 2s. 11d. per lb.; dealers holding spot supplies of good quality are firm at these rates. **Sulphonal,** about 14s. 6d. per lb., nominal; no interest is shown in importers' offers at this price. **Terpin Hydrate,** about 1s. 9d. per lb.; the spot position keeps very steady, but business is slow. **Thymol,** about 15s. per lb.; dealers offering imported material at about this figure.

Coal-tar Products, Intermediates, Etc.—Business has remained on the quiet side in these articles during the past week. Prices quoted show very little change, but in some directions the market is rather unsteady. **Aniline Oil,** about 9d. to 9½d. per lb., drums free; prices quoted are level, with the market quiet. **Aniline Salt,** 9½d. to 10d. per lb., casks free; the market is maintained at this quoted figure. **Beta-naphthol,** 1s. 1d to 1s. 2d. per lb.; any business would probably be at slightly less. **Benzol,** 1s. 4d. per gallon, f.o.r. makers' works, in buyers' packages; this item is now very steady, and the price is not likely to change again for some time. **Toluol,** 1s. 9d. per gallon, f.o.r. makers' works, in buyers' packages; a steady tone is maintained, despite the poorness of business. **Xylol,** pure, 2s. 3d.; commercial, about 1s. 6d. per gallon, drums extra; the demand for this product remains small; quoted rates unaltered. **Naphtha,** about 1s. 5d. per gallon; the price as quoted seems difficult to maintain, with the market dull. **Solvent Naphtha,** 90/160, 1s. 5d. per gallon, drums extra; prices quoted are the same; inquiry very poor. **Heavy Solvent Naphtha,** 90/190, 1s. 4d. per gallon, drums extra; the market is still flat, with quoted rates unsteady. **Special Oil,** for Diesels and motors, 10d. per gallon, barrels free; there is no change in the position on the week. **Burning Oil,** crude, No. 3, 8½d.; No. 2, 8d. per gallon, barrels free; business remains very small, and prices are level on the week. **Creosote Oil,** 10d. per gallon, f.o.b.; this market shows but little activity, but values are fully maintained. **Carbolic Acid,** crystals, about 1s. 2d. per lb., f.o.b.; at this price the position is now very sound. **Naphthalene,** £20. per ton; prices are being kept up to this level fairly well, with business poor; crude, £7. to £13.; crystals, £21.; powder, about £17.; balls, £28.; candles, £34.; tablets, £34. per ton, packages free. **Disinfectants,** 3s. 9d. per gallon, barrels free; inquiry continues, with quoted prices unchanged. **Pyridine,** 19s. to 20s. per gallon; nominal; it is doubtful if there are stocks of any size to meet the good inquiry on the market; prices are very sound. **Hexamethylene,** 4s. to 4s. 3d. per gallon; the spot prices are well up to these levels. **Pure Methyl Alcohol,** £100. per ton, ex wharf London; the market here keeps very steady at this rate. **Pitch,** about 135s. per ton, spot London; a steady market seems to have set in here; inquiry is limited.

LONDON METAL MARKET. Wednesday.

Copper: Standard brands, £63. 15s. to £63. 17s. 6d., cash; £64. 10s. to £64. 12s. 6d., three months; electrolytic, £69. 5s. to £69. 15s. **Tin**: Standard, £184. to £184. 5s., cash; £185. 5s. to £187. 7s. 6d., three months; Straits, £187. 10s.; English, £184. 15s. **Lead,** soft foreign, £23. 17s. 6d., prompt; English, £25. 5s.; chemical sheet, 34s. per cwt. for 2-ton lots, delivered. **Spelter,** prompt, £31. 17s. 6d.; hard, £25. 15s. **Antimony,** English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35. **Aluminium,** 98—99%, £115. to £120.; foreign, £110., c.i.f. **Nickel,** £130., delivered; £125. to £130. for export, f.o.b. **Mercury,** £9. 5s. **Bismuth,** 10s. **Platinum,** 500s. per oz. **Wolfram,** spot, 12s. 6d. to 12s. 9d. per unit, c.i.f. United Kingdom or Continent. **Zinc Dust,** quotations are as follows: Highest grade English, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET. Wednesday.

Business generally continues on the dull side, with a steady decline in values, and there are no signs of improvement. Quotations for **Alkali** products are maintained at recent rates: 70% Caustic Soda, £20.; **Ammonia Alkali** 58%, £7. 12s. 6d.; **Bicarbonate of Soda,** £10. 10s., bags, on rails works. **Soda Crystals,** £5. 5s., carriage paid. **Glauber's Salt,** easy at £4., carriage paid. **Bleaching Powder,** soft-woods, unchanged at £11. 7s. 6d. on rails. **Chlorates** are dull; **Potash** at 3d., and **Soda** 2¾d. per lb. **Bichromate of Potash,** 5¾d.; **Soda,** 4½d. per lb. **Copper Sulphate** is only moving off slowly, and price nominal at £26., f.o.b. Liverpool. American **Sulphur,** steady at £5. 5s. on rails. Quotations for **Phosphate** and **Hyposulphite of Soda** are lower, and demand small. **Nitrite of Soda,** firm at £26. 10s., ex store. White powdered **Arsenic,** scarce and dear at £75., delivered, for Cornish makes. Yellow **Prussiates** are weak; **Potash** 1s. 2¼d., and **Soda** 6½d. per lb. **Caustic** and **Carbonate Potash** have a downward tendency. Grey and brown **Acetate of Lime** are unaltered in position or value. Miscible **Wood Naphtha,** steady at 6s. 6d. per gallon. **Acetone,** firm at £125. per ton. **Acetate of Soda,** scarce at £24. 10s., ex store. **Acetic Acid,** in fair inquiry at recent rates. **Lead Salts** are unchanged: White **Acetate** £41., brown £43.; and **Nitrate,** £42 delivered. **Barium Chloride,** £15. per ton on rails. **Copperas** is moving off steadily, but values rule low. **Oxalic Acid,** lower at 5¾d. to 6d. per lb. **Permanganate of Potash,** 9¾d. to 10d. per lb.

SWANSEA MARKET REPORT. Wednesday.

More activity was displayed in **Tinplates,** and prices were firm on the basis of £1. 3s. 1½d. per standard box, f.o.b. **Galvanised Sheets,** fairly active on the average quotation of £17. 17s. 6d. per ton. **Copper,** moderately active at £63. 17s. 6d. per ton for prompt, and £64. 2s. 6d. three months. **Tin,** quiet and steady at £182. 7s. 6d. per ton prompt, and £183. 12s. 6d. three months for foreign; English, £183. 7s. 6d. per ton cash. **Lead** quiet, with better offers at £24. 2s. 6d. per ton cash, and £23. 17s. 6d. three months for soft foreign; English, £25. 7s. 6d. **Spelter** steady, with better inquiry; prompt, £30. 17s. 6d.; three months, £31. 2s. 6d. **Zinc Sheets,** easier at £38. 12s. 6d. per ton, on rail at works. **Sulphate of Ammonia,** quiet at fixed trade prices. **Sulphate of Copper,** dull at £26. 7s. 6d. per ton, less 5%. **Nitrate of Soda,** in better call at £13. 7s. 6d. per ton. **Bone Meal** steady, with prompt Indian at £9. 2s. 6d. per ton. **Linseed Oil** quiet, with raw, prompt, at £2. 3s. 3d. per cwt., net, in barrels. **Cottonseed Oil,** fair demand, with common edible at £2. 3s. 3d., and deodorised £2. 6s. 3d. per cwt. **Rape Oil** dull; prompt, refined, £2. 5s. 3d. per cwt., net, in barrels. **Cocoanut Oil,** very quiet at £1. 18s. 9d. per cwt. for Ceylon, prompt. **Olive Oil,** steady but quiet at £66. 17s. 6d. per ton. **Palm Oil,** quiet; Lagos, £33. 2s. 6d.; softs, £32. 12s. 6d. prompt, and forwards £32. 15s.; mediums, £32. 17s. 6d.; and hards, £33. 2s. 6d. per ton. **Turpentine** quiet, with American, prompt, at £3. 14s. 3d. per cwt. **Oxalic Acid,** dull at 6¼d. per lb. **Sulphuric Acid,** in fair demand at late rates. In the **Coal** trade, business seems to be settling down to normal, and full outputs are now to be expected: Best Admiralty smokeless £1. 9s. 6d., seconds £1. 8s.; ordinaries £1. 7s., all per ton, f.o.b. **Anthracite** trade good: Best large £2. 10s., seconds £2.; Paris nuts, £3. **Patent Fuel,** fairly active at £1. 10s. 6d. to £1. 14s. 6d. **Cokes,** less active at £2. 15s. 6d. for export; foundry, £2.; and furnace, £1. 10s. per ton.

LIVERPOOL CHEMICAL MARKET. Wednesday.

A somewhat freer inquiry for chemicals of the heavier kind has been noticeable, due apparently to the resumption of work in chemical-using industries after the stoppage in the early part of the month, for holidays, cleanings, and repairs. Shipments for foreign ports have been on a larger scale, and transactions in relation to them have helped to brighten up the market. **Bleaching Powder** has been rather more inquired for, and is £10. to £11. per ton, for use in the United King-

dom; and £11. per ton for export. **Calcium Chloride** has been in very fair request, business in this product being helped by the prevailing summer temperature; the price is £5. 17s. 6d. per ton. **Caustic Soda** has had a quietly steady sale on United Kingdom account, and has again had a very fair shipment for foreign ports; it is £20. 7s. 6d. to £21. 7s. 6d. per ton for 76% carriage paid, for home-trade uses; and £20. 10s. per ton for export. **Bicarbonate of Soda** has been in fair request for the home trade, and has been shipped more freely for export; it is £10. 10s. per ton, carriage paid, for use in the United Kingdom. **Soda Crystals** have had a moderate sale, and are £5. 5s. per ton for home-trade uses. **Nitrate of Soda** has had a steady though small sale, and is £13. 5s. to £13. 10s. per ton. **Borax** has been more in request for use in the United Kingdom; commercial crystals are £27. per ton, and powdered is £28.; higher grades are—crystals £31., and powdered £32. per ton, carriage paid in the United Kingdom. **Saltcake** has been quieter, and is £4. 10s. to £5. per ton for the home trade, and £5. to £6. per ton for export. **Bichromate of Soda** has been in moderate demand, and is 4½d. per lb., c.i.f. to usual ports. **Ammonia Alkali** has been steadily called for on home-trade account and has had a fairly large shipment on foreign account; the price is £7. 12s. 6d. per ton for home-trade use, and £8. per ton for export. **Hyposulphite of Soda** has been in rather good demand, and is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial; and £15. to £16. per ton in 1cwt. kegs for photographic. **Sulphide of Soda** has been very quiet; solid is £16. per ton, and crystals £10. 10s. to £11. per ton. **Chlorate of Soda** has been inactive, and is 3d. to 3½d. per lb. **Phosphate of Soda** continues very quiet, and is £15. to £15. 10s. per ton. **Prussiate of Soda** has had a slightly freer inquiry, and is 7d. per lb. **Yellow Prussiate of Potash** has had a steady inquiry, and is 1s. 2½d. to 1s. 3d. per lb. **Red Prussiate** has been but little in demand, and is 3s. 6d. to 3s. 9d. per lb. **Carbonate of Potash** has had a limited inquiry, and is £25. to £32. per ton, according to quality. **Nitrate of Potash** has been in fair request, and is £33. to £35. per ton for refined. **Chlorate of Potash** has been neglected, and is 3½d. to 4d. per lb. **Caustic Potash** continues quiet, and is £32. to £33. per ton. **Permanganate of Potash** has been more in request, and is 9¾d. to 10d. per lb. **Bichromate of Potash** has been but little inquired for, and is 5¾d. per lb., c.i.f. to usual ports. **Salammoniac** has been quiet; first quality is £63. per ton, second quality is £60., and third £57. **Sulphate of Ammonia** has had a slow sale for use in the United Kingdom, but has had a fair shipment; at date, the reduced price of £14. 5s. per ton for neutral of 25¾% is quoted, but from August 18 onwards to the end of September the price of neutral will be £14. 10s. per ton for use in the United Kingdom. **Carbonate of Ammonia** has been rather more inquired for, and is 4d. per lb. **Muriate of Ammonia** has been very quiet, and is £32. to £33. per ton. **Magnesia** has been more inquired for; **Carbonate** is £2. 5s. per cwt., and **Sulphate** £5. to £6. per ton. **Alum** has had a quietly steady sale, and is £12. per ton for home-trade uses, and £11. to £11. 10s. per ton for export. **Sulphate of Alumina** has had a moderate inquiry, and is £8. to £11. per ton, according to quality. **Sulphur** has been in fair demand; flowers are £10. per ton, roll is £8. 10s. per ton, rock £8. to £8. 10s. per ton, and American £5. to £5. 10s. per ton. **Tartaric Acid** has sold more readily, and is 1s. 2¼d. to 1s. 3d. per lb. **Cream of Tartar** continues in very fair request, and is £4. 12s. to £4. 15s. per cwt. **Boric Acid** has again had a quietly steady sale; commercial crystals are £52. per ton, and powdered is £58., £2. per ton extra being charged if in casks. **Citric Acid** has had a moderate inquiry, and is 1s. 7d. to 1s. 9d. per lb. **Oxalic Acid** has been but little in request, and is 6d. to 6¼d. per lb. **White Acetate of Lead** has moved but slowly, and is £42. to £43. per ton. **Sulphate of Copper** continues quiet in the home branch and in the export branch of the trade; it is £26. to £26. 5s. per ton, less 5%, in casks, f.o.b. at Liverpool. **Arsenic** has been but little inquired for; white powdered is £71. to £72. per ton.

WEST OF SCOTLAND CHEMICALS. Wednesday.

A little more activity has again been noticeable in the Glasgow market during the week, and business, though still of small dimensions, is considered as having a more hopeful tone. The usual day-to-day demand for chemicals on home account is maintained, but inquiries for export are still of a limited character. Prices generally are steady. Quotations, at Glasgow, are as follows:—**Alum**, quiet, and in small demand; prices steady at £12. 5s. for lump, and ground £12. per ton. **Arsenic** continues in short request, and supplies are still very scarce; the quotation is reduced to £76. 10s. per ton net on spot. **Barium Chloride** remains very quiet, despite the recent reduction to £15. per ton. **Bleaching Powder** does not show much movement, and the quotation stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax**, granulated, is on offer at £26. 10s. per ton net, in 2cwt. bags. **Calcium Chloride**, 70—75%, solid, £5. 12s. 6d. per ton. **Citric Acid** is a quieter market, with the price maintained at 1s. 7¼d. per lb., less 5%. **Copper Sulphate** is but little in request at last week's figure of £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar** steady, with better inquiry at £4. 8s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in fair request; brown steady at £41. per ton, net; and white better at £41. 10s. per ton, net. The market for **Magnesium Chloride** is slow, with quiet business at £3. for spot. **Oxalic Acid** is 6¼d. per lb. **Paraffin Wax** experiences a fair export trade at 2¾d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull at the steady figure of 1s. 3½d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1 11s. per cwt., but business is nominal. **Sodium Bichromate** remains steady, with business on the basis of 4½d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2cwt. bags; and £11. 10s. in 1cwt. kegs. **Tartar Emetic**, 43—44%, in fair request at 1s. 1½d. **Tartaric Acid** still shows a quieter tendency at 1s. 2¾d. per lb., less 5%, Glasgow.

IMPORTS OF CHEMICAL PRODUCTS

At the Principal Ports of the United Kingdom.

AMMONIUM NITRATE—
Rotterdam, 16 t., £432.

ANTIMONY SULPHIDE—
Antwerp, 2 cks., £14.; Bilbao, 3 cks., £48.; Hamburg, 7 cks., £70.; Trelleborg, 5 cks., £58.

BARIUM PEROXIDE—
Rotterdam, 41 drms., £450.

BISMUTH SUBNITRATE—
Piraeus, 1 cs. (pt.), £31.
Sydney, 2 cs., £205.

CADMIUM SULPHIDE—
Antwerp, 1 cs., £31.

CALCIUM CHLORIDE—
Zanzibar, 1 t. 5 c., £15.

CAUSTIC SODA—
Dunedin, 4 c., £17.

CHEMICALS (*otherwise undescribed*)
Calcutta, 10 pkgs., £50.; Constanza, 150 pkgs., £405.; Irish Free State (F.), 1 pkg., £12.; Limon (F.), 2 pkgs., £5.; Salonika (F.), 2 pkgs., £11.; Salonika, 8 pkgs., £22.; Sydney, 2 pkgs., £35.

CITRIC ACID—
Bombay, 2 c., £11.; Christchurch, 2 c., £19.; Colombo, 2 c., £21.; Gothenburg, 6 c., £51.; Rotterdam, 1 t., £192.; Stockholm, 5 c., £42.

COAL TAR PRODUCTS—
Creosote Oil
Delagoa Bay, 109 drms., £700.
Hamburg, 862 t., £8,206.
Napthhalene
New York, 500 bgs., £563.
Pitch
Lagos, 12 cks., £27.
Rouen, 84 brls., £237.

COAL TAR PRODUCTS—
Tar
Channel Islands, 100 cks., £220.
Tar Oil
Jamaica, 5 brls., £19.

CREAM OF TARTAR—
Fremantle, 1 t., £88.

DISINFECTANTS (*otherwise undes.*)
Malaga, 11 c., £15.
Melbourne, 1 c., £12.
Rosario, 7 t., £282.

DYESTUFFS (ARTIFICIAL)—
Unspecified
Irish Free State (F.), 1 cs., £23.

FERTILISERS (*otherwise undes.*)—
Gothenburg, 1 t., £25.

IODINE—
Paris (F.), 20 kgs., £1,756.
Piraeus, 1 cs., £103.

MERCURY OXIDE—
Amsterdam, 2 cs., £77.

METHYL ACETATE—
Paris (F.), 18 drms., £340.

NITRIC ACID—
Huelva, 3 c., £13.

POTASSIUM IODIDE—
Piraeus, 1 cs. (pt.), £18.

PRUSSIAN BLUE—
Brussels, 3 cks., £75.
Rotterdam, 10 cks., £101.

SALICYLIC ACID—
Brisbane, 2 cs., £25.

SALTPETRE—
Amsterdam, 1 t. 5 c., £54.
Vigo, 10 c., £20.

SODIUM BICARBONATE—
Paris, 2 c., £7.

SODIUM BISULPHITE—
Rotterdam, 10 t., £213.

SODIUM SALTS (*otherwise undes.*)
Sydney, 4 c., £8.

SULPHURIC ACID—
Aden, 3 c., £17.
Channel Islands, 15 c., £20.

TARTARIC ACID—
Gothenburg, 10 c., £64.; Lisbon, 10 c., £64.; Paris, 1 c., £18.; Rotterdam (F.), 10 c., £65.; Stockholm, 4 c., £26.

Week ending August 11.

BENZINE—
Reval, 33,568 galls.

FULLER'S EARTH—
Rotterdam, 50 t.

GLUE, SIZE, AND GELATINE—
Adelaide, 1 c.; Amsterdam, 2 c.; Christiania, 1 t. 8 c.; Rangoon, 1 c.

LEAD ASHES—
Antwerp, 3 t.

PLUMBAGO—
Pt. Elizabeth, 1 t.

SALT—
Gothenburg, 2 t. 8 c.
Valparaiso, 8 c.

SHELLAC—
Italy, 1 t. 17 c.

SOAP—
Accra, 1 t.; Addah, 2 t. 3 c.; Adelaide, 1 c.; Bagdad, 2 c.; Bombay, 18 c.; Christchurch, 1 c.; Cuba, 3 c.; Gibraltar, 2 c.; Limon, 1 c.; Lisbon, 2 c.; Melbourne, 6 c.; Paris, 1 t. 17 c.; Perth, 1 c.; Rangoon, 1 c.; Rotterdam, 13 c.; Sekondi, 15 t.; Winnebah, 4 t. 15 c.

TALLOW—
Dusseldorf, 10 t. 7 c.; Hamburg, 10 t. 2 c.; Pasages, 3 t. 1 c.; Rotterdam, 10 t.

WHITE LEAD—
Belize, £13.

MANCHESTER.

Week ending August 10.

ALUM—
Montreal, 10 cks.

AMMONIUM SALTS (*otherwise undescribed*)—
France, 14 cks.

BARIUM CHLORIDE—
France, 100 bgs.

BLEACHING POWDER—
Gothenburg, 3 kgs.

CALCIUM CHLORIDE—
St. John, 30 drms.

CHEMICALS (*otherwise undescribed*)
Basrah, 8 kgs.; Canada, 250 kgs.; Denmark, 20 drms.; France, 30 bgs.; Jersey, 440 sks.; Sweden, 4 cs., 25 drms.; U.S.A., 25 drms.

COAL TAR PRODUCTS—
Anthracene
Rouen, 1 kg.
Naphthalene
Cologne, 694 bgs.
Philadelphia, 650 bgs.
Unspecified
Czecho-Slovakia, 1 cs.

DYESTUFFS (ARTIFICIAL)—
Alizarine
France, 4 cks.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	19s. 6d.	24s.
Half-yearly (26 numbers)	10s. 6d.	13s.
Quarterly (13 numbers)	5s. 6d.	7s.

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."
Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.
Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

CURRENT TOPICS.

THE FORMALDEHYDE DECISION.

ELSEWHERE in this issue we print the full text of the decision in the formaldehyde case. As will be noted, the referee has found the material to be neither an analytical reagent, a synthetic organic chemical, nor a fine chemical, and in consequence not to be entitled to the protection afforded by Part I. of the Safeguarding of Industries Act. He recognises, however, that formaldehyde is one of those border-line cases upon which different opinions will inevitably be held. With regard to the analytical-reagent point, few will be disposed to disagree with the referee's finding, and the weight of the evidence that was presented was certainly against formaldehyde being considered a fine chemical. Yet we venture to suggest that had a referendum been taken amongst chemical manufacturers, merchants, and chemists two or three years ago, before attempts had been made to define the term "fine chemical" and when no financial interests were at stake, formaldehyde would have been held to be a fine chemical by a large majority. The case, however, centred mainly round the meaning to be attached to the words "synthetic chemical." From the purely logical and etymological standpoints, the position taken by the complainants and adopted by the referee in this and previous cases, that the term synthesis is confined exclusively to operations involving the bringing together of elements or radicles to form a more complicated body, is no doubt quite valid. The idea underlying this view is that any accepted synthesis in organic chemistry involves the addition of at least one extra carbon atom. Yet there are cases in which chemicals which are quite generally accepted as synthetic are produced by processes in which no extra carbon atoms are added to the molecule of the raw material. Alizarin as made from anthracene is a case in point, and there is little doubt that were the nature of alizarin investigated by the referee, he would be compelled to find the dyestuff not a synthetic organic chemical. In the literal sense of the word, production of an organic compound by the controlled and regulated oxidation of another organic compound may not be a synthesis, but we think that when the term "synthetic organic chemical" was adopted by the framers of the Safeguarding of Industries Act the intention was that it should have the somewhat broader meaning which certainly includes formaldehyde within its scope.

THE DECLINING SUPERPHOSPHATE INDUSTRY.

The gravity of the situation with which British manufacturers of superphosphates are confronted is daily becoming more pronounced. Exports, it is true, have been a little better this year than in 1922, but the total quantity exported has been too small to make any marked difference to the position. Before the war, the British manufacturers had a very substantial export trade with South Africa, Australia, and New Zealand, but during the war period these colonies increased their manufacturing capacity to such an extent as to render them practically independent of imported supplies. In Australia, indeed, the Commonwealth Government has subsidised the industry by providing a bounty on the production of sulphuric acid to be used in the manufacture of the fertiliser, in place of the heavy import duties on sulphur which have been removed recently. It does not appear too pessimistic a view to assume that these markets must be regarded as permanently lost. The main cause of the prolonged depression in the British industry, however, is to be ascribed to the changing conditions in home consumption. The low and steadily depreciating value of the franc enables Continental manufacturers to sell here at prices actually below the cost of production in this country. It should be explained that the principal factor in favour of the Continental manufacturer is that the exchange has, generally speaking, fallen by sharp steps, with a fairly steady period in between each fall. The Continental manufacturer of superphosphate has thus always been able to calculate on a further fall in exchange before the previous fall has had time to become fully effective in increasing costs. Consequently he has been able to accept a lower and lower sterling price for his superphosphate without actual loss to himself. Prices which are now being quoted for the 30 per cent. grade, for example, are in some cases actually below the pre-war figure, and it is quite clear that such prices must entail a heavy loss to the home manufacturer. The question is, therefore, as to what steps should be taken to revive this industry which is so heavily handicapped by unfair foreign competition. A tariff on imported material would undoubtedly meet with strong opposition from the agricultural community, while assistance from the State in the form of a subsidy would add further to the heavy burden now carried by the British taxpayer.

INDUSTRIAL OXYGEN IN AMERICA.

Interest in the problem of the manufacture of cheap oxygen and of its large-scale utilisation in metallurgical operations has not been confined to this country, but a considerable amount of investigation on the subject has also been carried out in the United States. Some time ago the American Bureau of Mines appointed an Advisory Committee to consider the question of the application of oxygen in the metallurgical and allied industries, and this committee has just issued a report which contains several interesting points. It will be remembered that Mr. T. Campbell Finlayson in the paper he presented to the Institution of Chemical Engineers in June last showed that consequent upon the long series of investigations carried out by the Woodall-Duckham Vertical Retort and Oven Construction Company (1920), Ltd., it was concluded that there was no simple process capable of producing oxygen at a price not exceeding 1s. per 1,000 cubic feet at a low capital cost. The American committee, however, has arrived at the conclusion that to serve metallurgical processes directly, large oxygen-manufacturing plants can be built which, by virtue of their large production and correspondingly increased efficiency, together with the fact that no compression in cylinders, storage, transport, or service will be required, will be capable of delivering oxygen for the processes at a cost not to exceed three dollars per gross ton. The oxygen is to be of about 99 per cent. purity and, for purposes of comparison with Mr. Finlayson's figure, the American cost works out at a little over 6d. per 1,000 cubic feet. The details that have enabled the American committee to estimate this surprisingly low figure are not yet available, but the committee is apparently confident in its expressed opinion. The British conclusions were only arrived at after a most comprehensive survey of the whole problem, and although the American forecast may eventually be proved to be too optimistic, yet the difference between the two prices is so great as to merit the closest attention in this country.

LOW-TEMPERATURE CARBONISATION IN VERTICAL RETORTS.

The possibility of using some form of vertical retort for low-temperature carbonisation and so arriving at mechanically operated continuous working with a consequent saving in labour costs, has always been an attractive one, and if the preliminary results that have been obtained by the Fuel Research Board in its work on this subject are any guide, the possibility would seem certain of eventual realisation. The Board has just published these results, which have been obtained in the plant of four Glover-West vertical retorts originally provided for experimental work in connection with ordinary coal-gas manufacture. Naturally the construction of these retorts, especially their lining of refractory material, is not particularly suitable for carbonisation at temperatures in the neighbourhood of 600° C., where rapidity of heat transference and maximum utilisation of the available heat are essentials. The results, however, have proved of the utmost value in providing data for the design of special vertical retorts for low-temperature work. Several of these special retorts have already been erected, and the detailed results obtained by working with them will be awaited with interest. Meanwhile the preliminary work has demonstrated clearly that results quite comparable to those obtained with horizontal retorts may be expected. On one point, indeed—namely, the production of ammonia—it would appear that the vertical retorts are likely to give the higher yield, particularly with a moderate amount of steaming.

MODERN ELECTRICAL PYROMETRY.

By David Brownlie, B.Sc., M.I.Mech.E.

THE accurate measurement of high temperature being a matter of particular importance to the chemical industry, an account of the great developments that have taken place in electrical pyrometry should not be without interest. Experience in methods of temperature indicating and recording in many industries, especially in connection with coal carbonisation and gasification, foundry work, furnaces of every description, and in the generation of steam and power, has demonstrated clearly the many advantages that this type of instrument possesses in practice. These include extreme accuracy at very wide ranges of temperature, comparative freedom from breakdowns, and convenience, the use of an electric current lending itself particularly well to both indicating and recording instruments, whilst the readings can be taken at almost any distance.

Limitations of Glass Mercurial Thermometers.

For continuous high-temperature work, say above 600° F., and especially above 900-1,000° F., glass mercurial thermometers are of course not suitable. It is true that we can use a special very tough and resistant boro-silicate glass, protected by a heavy metal case and stem, and with the space above the mercury filled with nitrogen, or other inert gas under high pressure, whilst recording mercurial thermometers are also available, but in practice this general type of instrument is nothing like so suitable as the electrical pyrometer. Glass mercurial thermometers are too fragile, the glass softens at high temperatures, and inaccuracies due to permanent distortion of the bulb are very liable. Another type of mercurial pyrometer, somewhat more satisfactory, is a steel pointer, consisting essentially of a bulb of mercury, with a capillary tube in the form almost of a wire, attached to a hollow tube as a flat hollow spring. The whole circuit is filled with mercury, and on heating the pointer the expansion of the mercury causes the spring to uncoil so that it actuates a pen mechanism. It may be stated also that the old-fashioned pyrometer, depending on the expansion of different materials—one common example being the iron and graphite pyrometer—can now be regarded as obsolete.

The Two Main Types of Electrical Pyrometers.

Electrical pyrometers may be divided into two main classes, the thermo-electric and the electrical resistance. The thermo-electric pyrometer, originally introduced by the distinguished French scientist, Le Chatelier, is based on the principle that if two dissimilar metals are joined together, the circuit completed by a wire and the junction heated, a very small electric current flows round the circuit. Different metallic couples—and Le Chatelier originally used platinum and rhodium—produce a different amount of current, but for any given couple the amount of current flowing is directly proportional to the temperature of the junction, although in practice temperatures of less than about 100° F. cannot be determined by this method.

Principles of the Thermo-Electric Type.

A thermo-electric pyrometer, therefore, consists essentially of a steel pointer containing the couple inside at the end, connected by wires to a delicate galvanometer which measures the amount of current flowing in the circuit by means of a pointer over a scale (indicating) or a pen upon a chart (recording), the graduations being direct as degrees of temperature instead of in electrical terms. Thermo-electric pyrometers, whether indicating or recording, can also be divided into two general types, depending on the composition of the thermo-couple.

For the very highest temperatures—from, say, 1,500-3,000° F.—the best metals are undoubtedly those of the highly resistant platinum group, such as platinum-platinum iridium alloy, or platinum-platinum rhodium alloy. These junctions are practically indestructible, and apart from the necessity of their use for very high temperatures, my own experience has been that they are much preferable in practice even for much lower temperatures—say, 500° F. and over—in the case of constant work. Of course, since the war it has been almost impossible to obtain the platinum metals, but this situation cannot be permanent. It must be remembered also that, although the initial cost is very high, the net expenditure spread over many years—and I myself have used platinum-platinum iridium couples more or less continuously for ten years—is practically nil, whilst the metal, like gold, always has a high market value, so that the expenditure is really more in the nature of an investment.

For temperatures below about 1,500° F., however, it is more usual to employ for one element, other alloys which are the speciality of the various firms, typical examples being "Titan" and "Constantan" alloys, using as the other

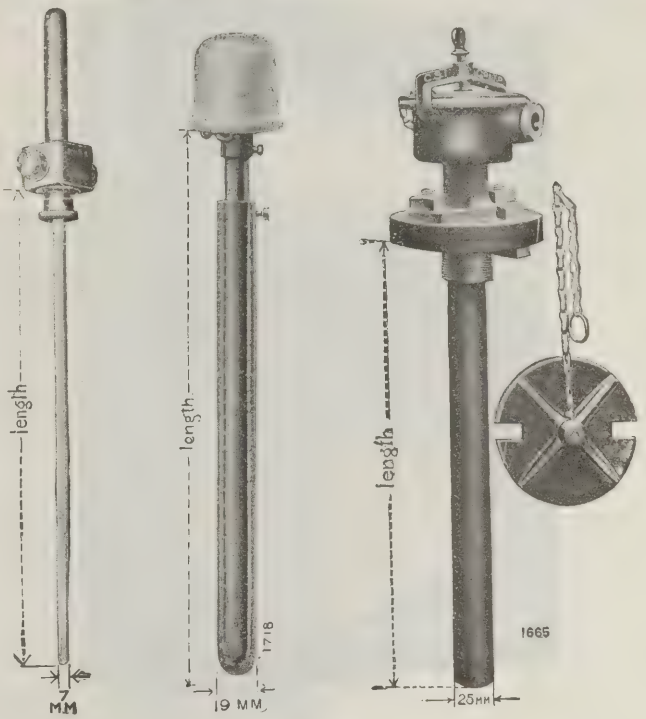

FIG. 1.

element generally copper, or sometimes iron. Probably the most widely known base metal, thermo-couple, is the "Chromel-Alumel" couple, which was introduced by Hoskins many years ago. In this couple one element is an alloy of nickel and chromium, and the other element practically pure nickel. Its composition is identical with that of "Titan." Such couples in time oxidise and disintegrate under the influence of the continued heat, especially when over 1,000° F., and have to be replaced, although the initial cost is naturally very much lower than that of the platinum metals.

Types of Thermo Couples.

In general, the thermo couple is constructed in the form of wires fused together and contained in a tube or segments of porcelain or silica ware tubing within the steel pointer for insertion in the source of heat. If the temperature is very high or the atmosphere corrosive, the pointer may be constructed of fireclay, or even of fused silica ware. The head of the pointer is equipped with two screw terminals to which are attached the wires (covered with canvas or rubber) connected to the galvanometer, which, provided the wires have been standardised, may be a fair distance away, say 25-50 yards. The instrument can be calibrated for accuracy in the usual way by using the vapour of any substance boiling at a high temperature, such as aniline, naphthalene, or even metals, and it is best to carry out the test using a standard length of wire, which must then always be used, being coiled up if the distance is short.

In the accompanying illustration (Fig. 1) three types of thermo couples made by the Cambridge and Paul Instrument Company Limited. are shown. The one on the left is the standard thermo couple for laboratory use. Here the wires are only protected by a single tube of porcelain or quartz, and the head is so constructed that new tubes can be readily fitted. The standard length is 12 inches. The

thermo couple in the centre is of the iron-constantan type for temperatures up to 800° C. The wires are protected by a steel tube and an outer removable steel sheath. The thermo couple on the right is for measuring temperatures in hot air mains and of the outgoing gases of blast furnaces. The wires are protected by a quartz tube and a steel sheath which fits into a flanged socket; this socket is threaded 1½in. gas for screwing into the main. The couple has an enclosed

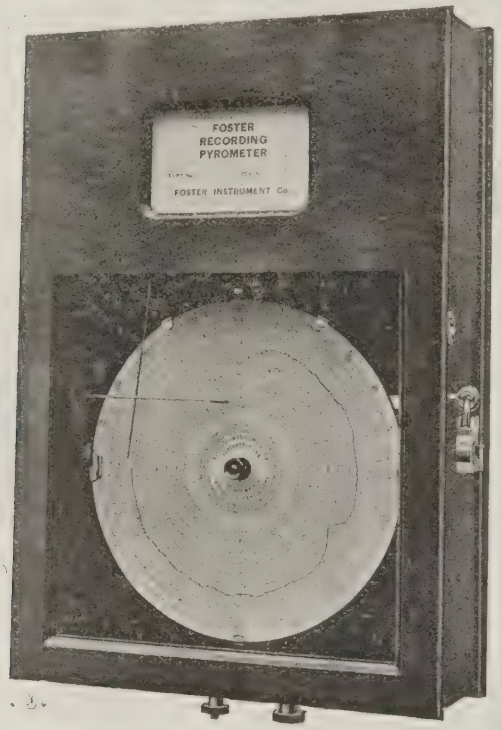

FIG. 2.

head, the cover being provided with a cap which can be quickly removed for making or inspecting connections.

The galvanometer, which may be either portable or of the wall type, is usually of a very robust construction, the dead-beat sensitive moving coil being pivoted between two jewel bearings, and contained in a cast-iron case, having in the case of indicating instruments a silvered metal scale protected by glass, over which the needle moves. Considerable differences in detail exist between the various makes of

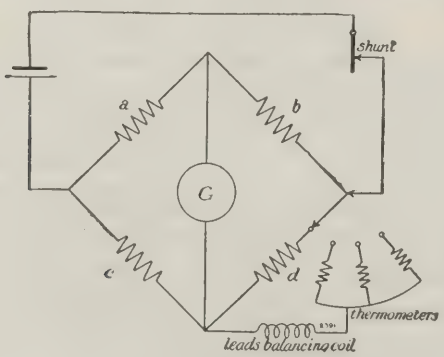

FIG. 3.

instrument on the market. Figure 2 represents one of the types manufactured by the Foster Instrument Company. For wall instruments a switch can be provided, so that any number of pointers may be used wired up to a central switch-board, although, as already stated, the range is somewhat limited as regards distance.

Distance Electrical Pyrometers.

Distance electrical pyrometers, as their name implies, are adapted more particularly for indicating or recording small or moderate temperatures at a considerable distance from the galvanometer, and are also specially suitable for permanent installation. In the case of a considerable length of wire being necessary, the amount of current generated by thermo-electric means is not sufficient for accurate results, and consequently in the distance pyrometer an entirely different system is adopted. The principle depends on the fact that the resistance of a coil of platinum or other wire varies with the temperature according to a well-known law. Consequently a comparatively strong current from an accumulator is sent continuously through the complete circuit, thus obviating all troubles due to the length and resistance of the circuit. A standard coil is contained in the end of the pointer, in which, when heated, the resistance to the passage of the current varies in proportion to the temperature. Generally the wiring for a permanent installation is such that the pointer forms one of the four arms of a considerably modified "Wheatstone" bridge, which is coupled to the galvanometer, the other three arms being composed of some material the resistance of which is not affected by the temperature, these three arms being of course at ordinary atmospheric temperature and away from the source of heat. Figure No. 3, of the Cambridge and Paul Instrument Company, Limited, illustrates diagrammatically the principle of the distance electrical pyrometer.

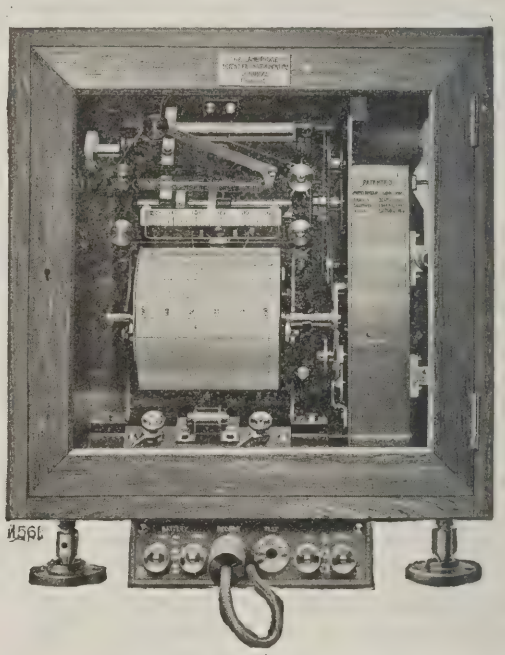

FIG. 4.

The circuit is supplied by a small 2-volt. or 4-volt. accumulator, which is recharged as required, and when all four arms are at an equal temperature—as when the pointer is in the atmosphere—an equal current flows down each side of the circuit, consisting of two of the arms, and the galvanometer in the centre is not affected. Since the current is divided in this way equally into two in the "Wheatstone" bridge, any variation in the strength of the current does not affect the needle of the galvanometer. If now the pointer is heated, the resistance of the standard coil alters, and more or less current flows down one side of the circuit, and since this means an inequality in the two arms, some current flows through the galvanometer and causes the needle to move. The instrument is so constructed that this movement is proportional to the temperature, and the galvanometer—in the case of an indicating instrument—is graduated direct in degrees F. or C. Figure 4 represents a recording distance electric pyrometer manufactured by the Cambridge and Paul Instrument Company.

This type of instrument differs also from the thermo-electric type in that the range of temperature is very

different, generally about — 350° F. to + 1,750° F. as compared + 100° F. to + 3,000° F. That is to say, the electrical distance pyrometer will measure with great accuracy, at any distance, all temperatures from as low as — 350° F. to about 1,750° F. because the resistance of the coil varies proportionately within these limits, whereas a thermo-electric pyrometer operating only at a comparatively short distance is not suitable for low temperatures, but has the advantage of being applicable to extremely high temperatures. It might be mentioned here that the Foster Instrument Company make a type of distance electric pyrometer which does not require adjustment to "test point" for change in battery voltage.

A Typical Boiler and Power Plant Installation.

A typical installation of the electrical distance pyrometer is a boiler and power plant. The indicating galvanometer is mounted on a black enamelled slab panel, and wired to the accumulator near at hand. The panel is provided with any number of plug holes, and each of the small insulated metal casings in which these holes are situated are wired permanently to different pointers at various portions of the plant. For example, take the case of an installation of two-water-tube boilers and accessories such as air heaters, superheaters, and economisers, and driving a pass-out steam turbine, a typical installation for a very modern chemical works. Pointers made of any desired length, from several inches in the case of pipe circuits to six or seven feet for flues, are inserted in all the necessary positions, such as in the flue gases after the boiler and superheater, after the economiser, and after the air heater (6 pointers for the two boilers), and perhaps also one pointer in the final chimney base. As regards water, the positions would be, say, before and after the economiser on each boiler, together with the condenser water inlet and outlet, 6 pointers in all, whilst four other pointers are required for the air supply (before and after heating) on each boiler. Then as regards the steam, there would be one pointer in the outlet pipe from each boiler installation, and one at the stop valve of the turbine to keep a check on the temperature drop in the steam from the boiler to the turbine. This would make in all 20 pointers, which would each be separately wired up to one panel with 20 plugs, or still better perhaps to two panels of 12 plugs each, giving a number of spare plugs. The whole of the temperatures can then be logged in a few minutes by inserting a hand plug in each of the holes in succession and reading the galvanometer accordingly. The arrangement is extremely convenient, and has the further advantage that since a current is always flowing any defect in the circuit is made obvious at once. A switch panel for distance electric thermometers as made by Negretti and Zambra, Ltd., is illustrated in Figure 5.

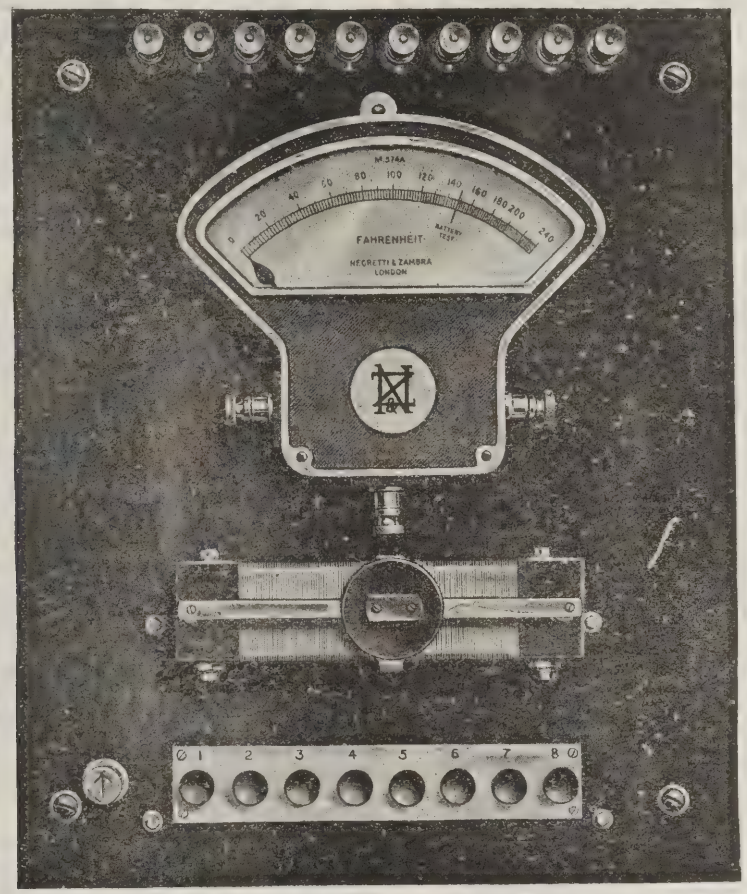

FIG. 5.

Typical Thermo-Electric Pyrometer Installations.

As typical also of the many possible applications of modern thermo-electric pyrometers to the chemical and similar industries Fig. 6. shows an installation by Messrs. The Foster Instrument Company of six different pyrometers, which can be coupled to one central switchboard. No. 2 could be a tar still or vessel containing varnish, bitumen or various oils with a temperature range of 0-750° F. (0-400° C.), having a 36in. pointer of $\frac{5}{8}$in. with a collar (U^3), protected by an outer sheath (P^{25}) of any desired material resistant to the conditions. No. 3 is a typical pointer installation for flues, enamelling ovens, biscuit ovens and similar work, with a temperature range of, say, 0-750° F. (0-400° C.). In this case the pointer is 36in. long inserted in the top of the flue as shown, held in position, by a flange (K^3) of $4\frac{3}{4}$in. outside diameter, with a "connecter" C^1 at the top of the pointer. Installation No. 4 is for apparatus such as oil tempering baths, varnish vats, or comparatively low temperature molten salts or metals with a temperature range of 0-1,200° F. (0-650° C.) having a bent pointer L for convenience attached to the bath by a clamp hook J^3. No. 5 is a typical installation for a hot gas main, say producer gas, water gas, or blast furnace gas, with a range up to 1,200° F. (650° C.) or 1,900° F. (1,050° C.), having for convenience a bent pointer of steel sheathing. Installation 6 is for baths of lead, aluminium, and general low temperature alloys and

for molten salts up to 1,652° F. (900° C.); and this type of installation is also supplied for temperatures up to 2,400° F. (1,300° C.) as in barium chloride baths. Finally, No. 7 is a general installation for small furnaces, such as hardening, tempering, and general experimental work, with a range up to 1,900° F. (1,050° C.), having a bent pointer.

Advantages of Recording Instruments.

For special requirements, particularly when only a few pointers are necessary, as in the case for example in many chemical reactions such as sulphonations, nitrations, or general rectification or autoclave work, the arrangement can be made recording. That is to say, the galvanometer is of the recording type, on the principle, for example, of a needle or short pointer depressed at very short intervals, giving a row of dots on a chart. By the use also of different coloured ribbons and an automatic arrangement, one galvanometer can be used for two or three pointers, each pointer operating a different coloured ribbon, or twin galvanometers, giving, say, 4 records, can be obtained in one casing.

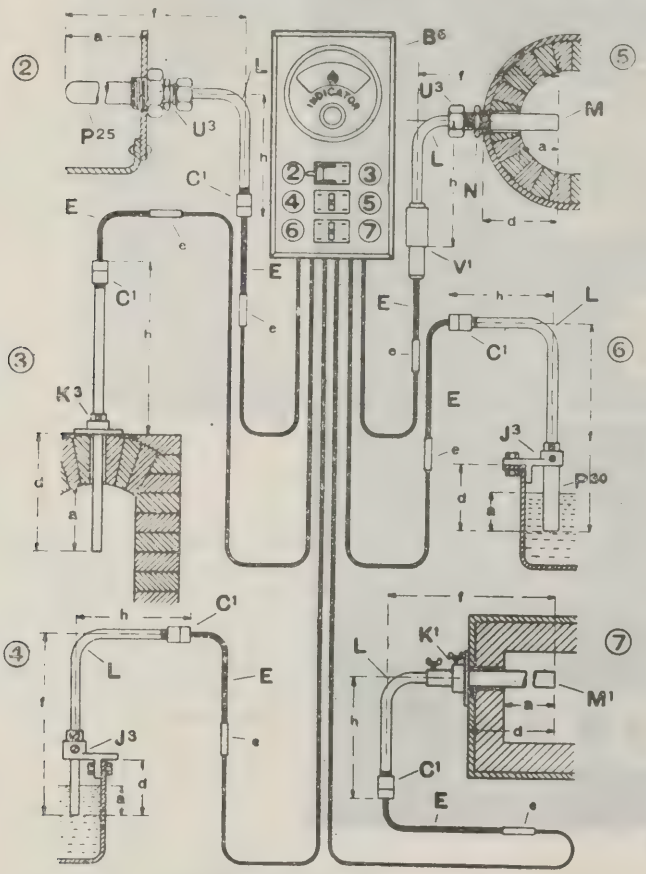

Fig. 6.

In general, there seems to be a considerable amount of prejudice against the use of recording electrical pyrometers, and, in spite of the extending use of modern indicating pyrometers, nothing like sufficient use is yet made of these invaluable aids to efficiency. Represented by the recording type, they are usually regarded as being too complicated and liable to breakdown, and also in the nature of an expensive luxury. It can only be stated that recording pyrometers of reputable make are no more trouble than many other scientific instruments in general use in the chemical industry, and a continuous record of temperature for many operations is very desirable. In return for the advantages secured and the fine workmanship necessary in the construction, the capital outlay is infinitesimal, and altogether a recording electrical pyrometer is a striking indication of the fact that the relatively small cost of most instruments of precision is entirely out of all proportion to the benefits received by the user.

Electric Radiation Pyrometers.

It may also be stated that the electrical principle has been adopted in connection with radiation pyrometers, although this is a very special section of the subject. Briefly speaking, however, a modern radiation pyrometer, such as constructed by Messrs. The Foster Instrument Company, consists essentially of a receiving tube or telescope, which is held up in front of the hot body—as, for example, a mass of white hot steel, or the interior of a kiln or other furnace—at a considerable distance away. This receiving tube is wired by flexible connections to an indicating galvanometer, which is graduated to read direct in degrees Fahrenheit or Centigrade. Expressed shortly, the principle consists in the fact that in the receiving tube or telescope there is a series of lenses or mirrors, which focus the heat on to a central spot, which then generates current in a special delicate thermo-electric couple, and this current is a measure of the amount of heat, affecting the galvanometer in the ordinary way.

PHYSICO-CHEMICAL STANDARDS.

BELGIAN AND AMERICAN MATERIALS AVAILABLE.

THE Bureau of Physico-Chemical Standards, established by the International Union of Pure and Applied Chemistry, with headquarters at the University of Brussels, has samples of the following standard substances available for distribution to the chemists of those countries belonging to the Union:

(A) Standard substances prepared at Brussels and intended primarily for the calibration of low-temperature thermometers.

The freezing points of the following substances reproduce to 0.1° C., the scale of the helium thermometer of the Cryogenic Laboratory of the University of Leyden [*Compt. rend.*, 174, 365 (1922)]:

	°C.		°C.
Carbon tetrachloride	−22.9	Carbon bisulphide...	−111.6
Chlorobenzene	−45.2	Ether (stable form)	−116.3
Chloroform	−63.5	Ether (metastable	
Ethyl acetate	−83.6	form)	−123.3
		Methylcyclohexane..	−126.3

Fifty cubic centimetre samples of each of these substances are available at 25 Belgian francs per sample. All orders should be addressed directly to the bureau.

(B) Supplementing the preparations of the bureau are the following standard materials prepared by the U.S. Bureau of Standards at Washington and obtainable directly from that bureau [*Bur. Standards, Circ.* 25]: cane sugar, for calorimetry and saccharimetry; naphthalene, for calorimetry, benzoic acid, for calorimetry; sodium oxalate, for oxidimetry; dextrose, for use as a reducing agent; benzoic acid, for acidimetry; tin, zinc, aluminium, copper, and lead, with stated melting point, for use in thermocouple calibration.

The Bureau of Physico-Chemical Standards intends to act as a centre for the study of pure materials, and it requests that authors of papers in this field send reprints of their papers to the bureau. It also hopes that industrial organisations may be willing to contribute to the bureau materials which may be used as the starting point for the preparation of highly purified substances.

Available Chlorine in Bleaching Powder.—S. Ochi (*J. Chem. Ind.*, Japan, 1923, 26, 185) states that for the determination of available chlorine in bleaching powder Penot's arsenite method is generally considered to be the only trustworthy method, while Wagner's iodine method is held to give high results owing to the action of chlorate upon potassium iodide in the presence of hydrochloric acid. The author has found that by using 2—4 c.c. of dilute acetic acid (1 pt. of glacial acetic acid to 1 pt. of water) for 25 c.c. of the testing solution, the influence of chlorate in the iodine method is completely avoided. The arsenite method gives slightly lower results than the true value, while the iodine method gives somewhat high results. The accuracy of the two methods is of the same order, but when the testing solution or the standard solution is dilute, the iodine method is the more accurate.—*J.S.C.I.*

SAFEGUARDING OF INDUSTRIES ACT.

THE REFEREE'S DECISION IN THE FORMALDEHYDE CASE.

As reported briefly in our issue of last week, the referee has directed that formaldehyde be withdrawn from the list of dutiable articles compiled by the Board of Trade under Part I. of the Safeguarding of Industries Act. The withdrawal took effect from Monday, August 20. The proceedings at the hearings of the complaint were reported fully in the issues of the *Chemical Trade Journal and Chemical Engineer* of June 22 (page 756), June 29 (page 785), and July 6 (page 6). Below we give the full text of the referee's decision:

The question in this reference is whether formaldehyde is properly included in the list of articles dutiable under the Act. The case has troubled me a good deal because it raised three distinct questions as to every one of which I was asked to depart from, principles I had already laid down for my guidance. I do not say that I regard myself as bound by what I have said before. If I am satisfied in the light of further evidence that what I have said should be modified I will be quite ready to act on that conviction. But unless and until I am satisfied that the evidence given and accepted by me in earlier cases was wrong or that I misunderstood it I propose to adhere to the lines I have laid down.

It is said by the Board of Trade that the inclusion in the list of formaldehyde is justified: (1) Because it is an analytical reagent; (2) because it is a synthetic organic chemical; and (3) because it is a fine chemical.

Not An Analytical Reagent.

(1) It is very difficult to say when a chemical which has a use as an analytical reagent is within the Act, but of this I have no doubt, that unless a chemical compound has a real and substantial use as distinct from a nominal or occasional use as an analytical reagent it ought not to be included as such in the list. I am satisfied that the use of formaldehyde as an analytical reagent is too trifling to jusitfy its inclusion in the list as an analytical reagent.

Looseness with which the Word "Synthetic" is Used.

(2) I think that a good deal of confusion may arise unless one bears in mind that neither chemists nor books speak of synthetic chemicals. The expressions "synthetic perfumes" and "synthetic dyestuff intermediates" are doubtless in common use, but I think that the word "synthetic" is used quite loosely in the former case, and I am told by Sir Arthur Colefax and Mr. Parry that the expression "synthetic intermediates" has a special meaning referring to bodies from which synthetic dyestuffs can be obtained. The use of the word in this connection, therefore, throws but little light upon its meaning in the Act.

Various writers have defined the word "synthesis." The word describes certain methods of production of chemical compounds. I am asked by the opponents to say that if a chemical can be produced synthetically, that chemical is a synthetic chemical without regard to the question whether in any particular case the substance has been, in fact, so produced. In my opinion that is not the meaning of the Act. I think that the expression "synthetic organic chemical" means such chemicals as have, in fact, been produced synthetically. The results of the contrary view, if logically worked out, are so startling that I shrink from its adoption.

In my opinion the question to be determined in each particular case resolves itself into this. Has the substance on the importation of which it is claimed that duty is payable, in fact, been produced synthetically?

It is of course common ground that the synthesis of an organic chemical includes its "building-up" (to use Thorpe's expression) or its "formation" (to use Richter's expression) from its elements. It is equally clear that synthesis includes the "building up" or "the formation" from such carbon derivatives as can be obtained from the elements, but if the carbon derivative actually employed in the latter case as the raw material is one which, although, it could be, has not, in fact, been produced synthetically, it is contended, at least I understand that it is contended, that the resulting compound is synthetically produced without regard to the nature or character of the further building-up or formation from that raw material.

I am assisted in the decision of this point by the fact that there is no evidence to support the contention. Dr. Ormandy and Mr. Parry are at one on the point. To quote the former "the raw material must be one which could in case of necessity be produced through all the steps from its elements and the further step must itself be synthetic." I accept that view.

The Oxidation of Methyl Alcohol Not a Synthesis.

There then remains to be decided the question whether the step taken, namely the oxidation of methyl alcohol in the presence of a catalyst is truly described as synthesis. By this oxidation the methyl alcohol loses two atoms of hydrogen. Does this step partake of the nature of synthesis?

In two earlier cases great stress has been laid upon the contention that the essence of synthesis was a building-up or at any rate a bringing or placing together. The truth of that contention was one of the main issues in the camphor case. I quote the following passage from the opening remarks of Sir Arthur Colefax: "The Board of Trade are actually driven to this incredible position. Synthesis I have always until now understood merely as a matter of definition involved, adding something to or putting something together. But they are driven by the logic of their argument to this truly remarkable position, that synthesis is no longer to be putting two things together, but it is to be actually applied to a case where you take something away. It is a most remarkable use of the word synthesis, and certainly I should have thought nobody has ever held it." And later he put to his main witness the question: "Mere oxidation would never be talked of as a building-up?" He also asked the question in argument: "Where is the case that they can point to in which you can find general acceptance of the term synthesis, where the change does not involve an addition of a carbon atom?" I quote these passages to show how clearly the contention was raised on the one side in that case.

On the other side the Board of Trade submitted that the meaning of a synthetic organic chemical was a chemical produced by controlled processes resulting in molecular changes of any kind. Dr. Forster, called for the Board of Trade, objected to the expression "building-up" and argued that the true meaning was "placing together." He agreed that the generally understood meaning of synthesis was the bringing together of the component elements. He agreed that by the vast number of chemists to-day the bringing together of elements or radicles to form a more complicated body was their understanding of the term. On the evidence given in that case and on the arguments of Sir Arthur Colefax I accepted the view that synthesis, as generally understood, involved the bringing together of elements or radicles to form a more complicated body. I definitely rejected the contention that synthesis, as generally understood, included any molecular change so long as it was produced by controlled processes. I thought, and still think, that it is my duty to give to the words their commonly accepted meaning. Doubtless many chemists hold a different view.

Referee's Views from Earlier Cases Unmodified.

It is obvious that I cannot decide that the steps necessary for the formation of formaldehyde from methyl alcohol are synthetic without ignoring or reversing the view I took in the camphor case. It is to be noticed that no evidence was called by the Board of Trade or those supporting their view as to the meaning of synthetic or as to whether formaldehyde was or was not a synthetic chemical. Dr. Ormandy dealt with it in cross-examination only. He did not take quite the same view as Dr. Forster. He expressed the opinion that an operation was synthetic if it was a controlled reaction and it it gave proper yields—an entirely new suggestion. It is sufficient to say that no evidence has been given which satisfies me that the view I took in the camphor case was wrong. Incidentally that view is entirely consistent with the evidence given in the calcium carbide case.

No Evidence to Prove Formaldehyde a Fine Chemical.

I frankly admit that I should like to be able to decide that formaldehyde is a fine chemical. My difficulty is that I cannot find any ground upon which I can do so, consistently with what I believe to be the true principles applicable. It is quite clear on the evidence that this substance has not been commonly regarded as a fine chemical. The *Chemist and Druggist* definitely treated it as heavy; it appeared as heavy in Harris, Hart and Co.'s advertisements. Several lists were put in in which formaldehyde was classified as technical or general as opposed to fine. This may not amount to very much, but, on the other hand, not a single instance could be given of formaldehyde being called a fine

chemical or being classified as such before the Act of Parliament. An American paper of 1923 was produced in which it was classified as fine and the list of British fine chemicals published in 1922 includes it. Dr. Ormandy was not asked about it. Mr. Allen, called by the opponents, could only say that he did not regard it as a heavy chemical and that he did not understand the meaning of "fine."

No one was called from any of the big fine-chemical manufacturers. Two or three gentlemen were called who expressed the opinion that it was a fine chemical, but there was not any evidence at all that when this Act was passed formaldehyde had been regarded as a fine chemical in any branch of the trade. According to my decision in the tartaric acid case this finding ought to settle the case; but I think that one is driven to the same conclusion by a consideration of the other circumstances said to be relevant.

This chemical is not a pharmaceutical chemical. The opponents disclaimed any intention of putting it forward as such. It is an industrial chemical produced on a fairly large scale—a scale very large for a fine chemical. There is no doubt that most of the witnesses that have given evidence before me regard an industrial chemical used on a substantial scale as something very different from a fine chemical. Even representatives of May and Baker, and Howards, manufacturers of fine chemicals on a very large scale, take the same view.

A special plant is necessary for its production. It is handled in quantities somewhat big for a fine chemical.

On the other hand it is said that the formaldehyde on the market is of great purity and that its manufacture involves continuous scientific control. One has only to re-read the evidence in the earlier cases to see (1) that the degree of purity does not help very much; and (2) that the scientific control there described as necessary to stamp the product as a fine chemical was a control of highly-trained chemists as opposed to the skilled control of persons trained *ad hoc*, with the result that the cost of that control was high relatively to the total cost.

I am not at all satisfied that the skill required to produce formaldehyde is anything more than the skill of men taught and trained for the particular purpose, and Mr. Romanes said in his evidence that if you worked out the cost per ton of the scientific supervision you would find it very small.

I do not think that the description of the fine chemical group, Group 6 of the Association of British Chemical Manufacturers covers this substance.

Formaldehyde to be Removed from List.

The case is one of those border line cases upon which opinions will necessarily differ, but dealing with it as best I can on the evidence given, I find that the complainants have made out their case and that I must award that formaldehyde be excluded from the list.

REFEREE'S DECISION IN ROCHELLE SALT CASE.

The following is the full text of the referee's decision in regard to the complaint that Rochelle salt has been improperly included in the Board of Trade List of dutiable articles under Part I. of the Safeguarding of Industries Act: (the proceedings at the hearing of the complaint were reported in our issue for August 3, p.131.)

In my opinion no case has been made out for taking Rochelle salt out of the List. The Rochelle salt of commerce is a pharmaceutical chemical. It has also a well recognised use as an analytical reagent. It has practically no industrial use. I am inclined to think that the use as an analytical reagent in itself justifies the inclusion of Rochelle salt in the List, but I do not decide the case on that ground. Mr. Kenneth Swan's contentions may possibly require very careful consideration in some future case.

Rochelle Salt to Remain in the List.

I decide this case on the ground that there is no evidence to justify me in saying that the Board of Trade was wrong in including Rochelle salt in the List as a fine chemical. The fact that the chemical is used only in pharmacy and as a reagent raises a strong presumption that the trade would regard it is a fine chemical. Mr. Howard said that it was known in the trade as a fine chemical. Mr. Blenkinsop and others gave similar evidence. There was no trade evidence to the contrary. In my opinion there is no evidence that Rochelle salt is wrongly included in the List, and I award that the complaint fails.

THE MANUFACTURE OF SODIUM HYPOCHLORITE.

PRODUCTION OF CHEAP CONCENTRATED STABLE SOLUTIONS.

THE rapidly-growing demand for cheap sodium hypochlorite as a disinfectant of very general applicability, as distinct from its use as a bleaching agent for textiles has led to many efforts to prepare the material in the form of a highly-concentrated and stable solution suitable for transportation and storage. Up to the present the amount of success that has attended upon the efforts of workers in this field has not been very great, but a process has just been described by H. F. Zoller of the Nizier Laboratories Company, Detroit, U.S.A. (*Industrial and Engineering Chemistry*, August, 1923) which, if all the claims made in connection therewith are substantiated, would appear to have come very near to solving the problem. Mr. Zoller in his introductory remarks states, that: Our conceptions of the constitution and the physical and chemical behaviour of hypochlorite have very materially changed in the last few years. Recently, there have been a few attempts to regulate the stability and bleaching properties of chlorinated alkali solutions by studying their alkalinity in an empirical fashion. Among these investigations are the observations of Higgins that alkalies stabilise sodium hypochlorite solutions and lower the velocity of bleaching, while neutral salts increase the bleaching rate and decrease the stability. Renewed interest in hypochlorites, especially the alkali hypochlorites, for bleaching purposes in the textile industry has been strongly manifested in England during the last decade. In the United States the pendulum seems to have swung in another direction; we have become deeply interested in hypochlorites as sterilising agents and general disinfectants. Many factories engaged in the production of food products would use sodium hypochlorite as a sterilising rinse for their equipment, provided large quantities of a uniformly stable quality could be made readily available, but the present market price is prohibitive to a factory of any size.

Method Based on Hydrogen-Ion Control.

A method is here outlined which will enable the average factory to prepare its own effective disinfecting agent simply and cheaply. The method is based upon the hydrogen-ion control system of manufacture. The solution is heavily buffered in order that the reaction will not rapidly change to yield an unstable solution. A sodium hypochlorite solution containing 5 per cent. available chlorine is here considered to be a concentrated solution. Solutions containing 10 and even 15 per cent. available chlorine are readily prepared using the same principle, but they are unwieldy and impractical for general use.

The first successful attempts to prepare stable, dilute hypochlorite solutions for purposes other than bleaching were those of Dakin, and Cullen and Austin. These attempts matured in the introduction of a serviceable antiseptic solution for medicinal and similar uses, but, owing to difficulties co-existent with the transportation and application of the Carrel-Dakin solution, a series of chloramines was developed which has in a measure superseded the Dakin solution. Cullen and Austin found that between pH 9 and 10, Dakin's solution is very stable. This solution of sodium hypochlorite approximates a 0.44 per cent. solution of available chlorine, or a 0.45 per cent. solution of sodium hypochlorite.

Many attempts by others to prepare more concentrated solutions of sodium hypochlorite at a supposedly similar range of hydrogen-ion concentration (pH 9 to 10) have met with failure, the reason being, in the writer's estimation, a poorly buffered solution at the concentration sought. It is absolutely essential that the solution be heavily buffered between these limits of pH if a high concentration of hypochlorite is desired.

Direct Chlorination of Caustic Soda Most Suitable Method.

The methods in general use for the preparation of sodium hypochlorite are: (*a*) Double decomposition of calcium hypochlorite (chloride of lime) with sodium carbonate or sodium sulphate; (*b*) electrolysis of sodium chloride with the production of sodium hypochlorite and hydrogen; (*c*) direct chlorination of sodium carbonate with chlorine gas.

Wherever large quantities of sodium hypochlorite are demanded, the first process is undesirable because of the variable character of commercial chloride of lime, and

because of the large mass of residual calcium carbonate sludge which must be disposed of. In the electrolytic method it would be necessary to employ buffers along with the sodium chloride if a strong solution of sodium hypochlorite were desired; otherwise, it would be extremely unstable and the tax on the electrodes and equipment enormous. The direct chlorination method is the most practical one for universal practice in producing strong sodium hypochlorite solutions. It is the most easily controlled and can be effected rapidly on a commercial scale.

In adopting the direct chlorination method of manufacture, the first step was to provide a solution with sufficient buffer material to hold the hydrogen-ion concentration in the region of pH 10 to 10.5. On the assumption that the zone of reaction required for the stability of Dakin's solution was applicable to stronger solutions of sodium hypochlorite, several preparations of 2, 3, 3.5, 5, and 10 per cent. available chlorine were made and studied in regard to their stability. The results of the study showed that for maximum stability these strong solutions required that powdered phenolphthalein spread on their surfaces should show a faint but distinctly red colour, and further, that a 1 per cent. alcoholic solution of thymolphthalein should show a flash of blue colour. When such a solution is analysed for titrable alkalinity, available chlorine, and total chlorides, and calculations of the true hydrogen-ion concentration are made therefrom, one finds that the reaction is in the region of pH 10 to 10.6. This is a higher pH than is desired for Dakin's solution.

Sodium Carbonate the Best Buffer Material.

While all the buffer materials were serviceable, sodium carbonate, because of its availability and cheapness, proved superior. As far as could be estimated, there was no appreciable anion influence on the stability of the concentrated solutions among the above buffers. The criterion of the stability seemed to be the intensity of the alkalinity, which is here characterised as the hydrogen-ion concentration.

TABLE I.—Showing Relative Effect of Buffer Material (Anions) on the Stability of Sodium Hypochlorite.

60 per cent. Caustic Ash, Per cent.	Buffer.	Per cent. Buffer on Moisture-Free Basis.	Pink to Powdered Phenol-phthalein.	Blue Flash to 1 per cent. Thymol-phthalein.	Available Chlorine Fresh, Per cent.	Available Chlorine 30 Days Later, Per cent.
7·5	Na_2CO_3	2·5	Yes	Yes	3·25	3·25
7·5	Na_3PO_4	2·5	Yes	Yes	3·19	3·17
7·5	$Na_2B_4O_7$	2·5	Yes	(?)	3·20	3·21
7·5	Na_2SiO_3	2·5	Yes	Yes	3·22	3·22
7·5	$NaHCO_3$	2·5	No	No	3·25	2·80

The influence of daylight on the stability is only minor. The use of amber-coloured bottles is unnecessary. In ordinary clear glass bottles the hypochlorite solutions keep for 5 or 6 months with less than 10 per cent. loss in available chlorine. It is not necessary either to cool the alkali solutions below 40° C. while chlorinating them, or to store the resulting hypochlorite in a cold place. Whereas it is true that the activity of the hypochlorite solutions (chlorinating power) is accelerated by small increases in temperature, their internal decomposition is not noticeably accelerated at the stable region in pH 10 to 10.5.

When chlorine gas is passed into a mixed solution of sodium hydroxide and sodium carbonate, containing about 10 and 2.5 per cent., respectively, and the gas is stopped when the solution registers 5 per cent. of available chlorine, it is found that the yield is 99 to 100 per cent. A temperature change from 15° to 40° C. does not affect this yield. There is no permanent formation of either chlorate or perchlorate under these conditions. In actual experience a pure sodium-hypochlorite solution at pH 8 begins to lose free oxygen to the air. The higher the temperature at this pH the more rapid is the decomposition. Coincident with this loss of oxygen the solution becomes more acid, and because of the increased acidity the decomposition is again hastened. It is an example of catalysis augmented by the hydrogen-ion. Whether or not it is the chlorine or the oxygen, or both, which are the active constituents of sodium hypochlorite, for every pound of chlorine used, one pound (100 per cent.) of available chlorine is obtained in the product.

Details of the Manufacture and Control.

It was found desirable to use sodium hydroxide of good technical grade (60 per cent. caustic ash) for chlorinating, and a good grade of soda ash (anhydrous sodium carbonate) for the buffer material. In order to make a solution of sodium hypochlorite of certain strength, a definite amount of alkali in the presence of the buffer will be required to maintain the stable point in pH. A stronger solution will require more alkali. The writer has made several thousand gallons of 2.5 to 5 per cent. sodium hypochlorite during the last two years, and has found it desirable to maintain the concentration of sodium carbonate at the same point in all the formulas—viz., 2.5 per cent.

TABLE II.—Showing Relative Amounts of Alkali and Alkali Carbonate for Different Concentrations of Product.

NaOH (60 per cent. Free Alkali) Per cent.	Na_2CO_3 (Anhydrous Soda Ash), Per cent.	Average Chlorine for Stable Product, Per cent.	pH (Approx.). Per cent.
2·5 ..	2·5 ..	1·4 ..	10·0
5·0 ..	2·5 ..	2·25 ..	10·8
7·5 ..	2·5 ..	3·25 ..	10·5
10·0 ..	2·5 ..	4·50 ..	10·5
12·5 ..	2·5 ..	6·25 ..	10·6

For 5 to 25-gallon quantities of hypochlorite, the alkali and soda ash are weighed into an iron or copper bucket, and about one-third to one-half of the water is added and the whole stirred until dissolved. It is then filtered through layers of absorbent cotton or muslin into the chlorinating receptacle, which should contain the remainder of the water.

The chlorine is led from a commercial cylinder through a copper tube fitted with a brass or bronze needle valve, and silver soldered thereto. The copper tube may be made to fit snugly into the valve head on the chlorine cylinder and clamped there under pressure. The copper tube from the needle valve terminates into a gas meter, which is chlorine-tight. The meter may be either of the dump type or Venturi effect. Both have been used with success. They must be made entirely of glass and filled with a non-freezing, non-chlorine-attacking solution such as an alkali-chloride brine (NaCl). If rubber connections are used they will have to be frequently replaced. A chlorine distributor for immersion into the alkali solution may be made from a coarse alundum thimble and glass tube. By aid of the needle valve the stream of chlorine gas can be easily regulated. For large-quantity production the chlorine meter may be dispensed with, but it is then necessary to follow the rate of chlorination by titration.

It is only necessary to know the quantity of chlorine passing into the alkali during a given time interval to calculate the strength in terms of available chlorine. However, it is often more convenient to have available a 0.1 *N* sodium thiosulphate solution for the purpose of direct determination of the available chlorine content. The method used by the writer is to measure 10 c.c. of distilled water, 5 c.c of glacial acetic acid, and 5 c.c. of 5 per cent. sodium iodide into an Erlenmeyer flask. Exactly 2 c.c. of the hypochlorite solution are added, and the liberated iodine is titrated directly with the thiosulphate to the disappearnace of the yellow colour. No starch paste is necessary, although a white paper background is convenient. The number of cubic centimetres of 0.1 *N* sodium thiosulphate required for the 2 c.c. of chlorinated solution, multiplied by the factor 0.1772, will give the percentage of available chlorine in the sodium hypochlorite. The percentage of available chlorine multiplied by 1.05 is the percentage of sodium hypochlorite in the solution. It is very essential that the difference between the concentration of available chlorine and concentration of sodium hypochlorite be specifically stated. The two are often intermingled.

Relative Costs of Production.

The overhead expense of this method of manufacture is very low. Soda ash and caustic soda are relatively cheap—the former is around 2 cents per pound, and the latter about 4 cents per pound. Liquid chlorine is quoted at 7 to 10 cents per pound. Thus, if we allow 50 per cent. for labour costs, the expense of producing 2.5 to 5 per cent. "available chlorine" sodium hypochlorite amounts to approximately 6.80 cents and 16.22 cents per gallon, respectively. These values are in a marked contrast with the price of some of the commercial sodium hypochlorite preparations now on the market.

Barytes Production in the U.S.—During the year 1922, the barium products industries in the United States consumed 167,842 short tons of ore, from which were made 46,176 tons of ground barytes, 83,360 tons of lithopone, and 13,900 tons of barium chemicals having a total value of 11,398,000 dollars.

CASEIN IN THE PAINTS INDUSTRY.*

USE AS A BINDER IN DISTEMPERS.

CASEIN, one of the principal constituents of milk, was for long utilised only for alimentary purposes and its employment industrially is one of the greatest conquests of modern technology. It has only been with the growth in our knowledge of proteins and colloids in general and the light thrown thereby on the constitution of casein that this industrial advance has been made possible.

Conditions of Salt Formation with Casein.

Casein belongs to the group of phosphorus-containing proteins and also possesses several of the characteristics displayed by typical colloids. Thus, it is incapable of diffusing through those membranes which are easily permeable by crystalloids. Casein is an amphoteric compound, inasmuch as it will form definite chemical compounds with either acids or alkalies. With the former it gives salts such as nitrates, chlorides, sulphates, phosphates and acetates, and with the latter the caseinates of sodium, potassium, ammonium, calcium, barium, etc. These compounds however are only formed under definite conditions of hydrogen-ion concentration in the protein solution, and there exists a concentration above which no compound can be formed. This concentration is termed the isoelectric point and for casein is pH 4.7. In practice casein can combine with an alkali to form a caseinate when the pH is equal to 4.7, but can only combine with an acid when the pH is lower than 4.7.

When the conditions, as regards hydrogen in concentration, are favourable, the casein reacts stoichiometrically with the acids or alkalies forming salts which dissociate electrolytically. The incapability of casein solutions to diffuse through membranes permeable to the ordinary crystalloids is not due so much to the colloidal nature of the casein as to the enormous volume of the molecules.

Apart from the butter and the lactose, casein is the principal constituent of milk. It occurs therein as calcium caseinate in the form of a very finely-divided emulsion. This calcium caseinate also maintains in permanent suspension the neutral calcium phosphate contained in the milk; probably a double compound of the two salts exists in some cases. When the casein is precipitated the phosphate of lime is precipitated at the same time, whilst the fatty matters in the emulsion coalesce and separate out. It is thus difficult to obtain the casein free from fatty matters and calcium phosphate.

Casein Content of Typical Milks.

The casein content in milk is very variable. Whilst sheep's milk contains about 4.6 per cent., human milk contains but 0.5 per cent. The table below gives the percentage contents of the principal milks.

	Cow	Sheep	Goat	Ass	Mare	Human
Water	87.80	83.5	85.0	89.5	91.2	88.3
Casein .	3.20	4.5	3.7	0.8	1.3	0.5
Butter ...	3.50	5.2	4.7	1.6	1.0	3.0
Albumen .	0.30	1.8	1.3	1.9	0.8	1.7
Lactose ..	4.75	4.8	4.3	5.7	5.6	6.5

Commercially, cow's milk is the principal source of casein, and in such milk the casein content may vary from 2.5 to 4.2 per cent. The material used is the milk skimmed by centrifugal means. The Sharples and Hignette supercentrifuges enable a very complete skimming of the milk to be effected, leaving as an average little more than 0.02 to 0.15 of fatty matters in the milk. The average composition of such a skimmed milk is: water, 90.6 per cent.; casein, 4.26 per cent.; lactose, 4.22 per cent.; fatty matter, 0.13 per cent.; and ash, 0.78 per cent. Soya beans constitute a very valuable source of casein, but one which has up to the present, been but slightly resorted to. The greatest producers of casein are Canada and the Argentine which since the war have imported annually into Europe, thousands of tons of casein chiefly through the ports of Antwerp, London and Hamburg. France is also a producer of casein in small quantities but of the very best quality, and French casein is particularly esteemed for the manufacture of glues, for which purpose the complete absence of fatty matter is a desideratum.

The most interesting properties of casein are undoubtedly those of giving solutions possessing remarkable adhesive and agglutinating powers. The applications that casein has found are extremely varied and include the glueing of wood, the printing of textile fabrics and its use as a binder in paints. In the present article however only the use of casein in the preparation of colours and paints will be considered.

Precipitation and Drying of the Casein.

It was believed at one time that the casein obtained by precipitation from milk with acids was absolutely identical with that obtained by coagulation under pressure, but it has now been found that both physically and chemically there exists considerable difference between the two products, for whilst the substance precipitated by acids is true casein, that produced by pressure-coagulation is para-casein, a substance of less complexity than true casein.

Whichever method be adopted for separating the casein from the milk, however, the precipitate must be well washed with water to free it from any remaining milk and lactose, and then so treated as to reduce its water content. The clots are then broken up into fragments about the size of peas and dried at a temperature of 30-40° C. At a lower temperature, not only does the casein dry more slowly, but it is liable to ferment and to become covered with fungoid growths. If the temperature be much above 40° C., on the other hand, the casein undergoes profound modifications which lead to a darkening in colour and an appreciable diminution in adhesive power and solubility. The drying of the casein should be carried on until the water content is reduced to 10-12 per cent., at which point the material is easily friable and may be crushed to a powder in a wooden mortar. With a higher water content, the casein forms lumps which soon begin to decompose.

Commercial Grades and Common Adulterants.

The usual forms in which casein is met in commerce are as a fine flour and as a granulated meal. The fine powder is obtained by passing the dried casein through a porcelain ball mill or through fluted revolving cylinders. The forms in which the casein occurs as larger granules are made by spraying the product with a little alcohol before packing, with the addition of a little antiseptic to prevent fermentation. Good commercial casein is of slightly yellowish colour and possesses a faint unpleasant odour reminiscent of cheese. It is frequently adulterated with potato starch, barium sulphate, chalk, china clay, silver sand, dextrin, sodium sulphate, etc. A little aniline yellow is occasionally added to colourless caseins.

Soluble Casein.

Casein is insoluble in water, but may be solubilised by means of alkali. The soluble casein of commerce is casein to which has been added from 10 to 12 per cent. of borate or carbonate of sodium, or 20 per cent. of sodium bicarbonate. These mixtures are sometimes made in such a dilatory manner, that the naked eye can pick out easily the particles of the casein and the particles of the inorganic salt. This lack of homogeneity is frequently the cause of irregularity in the solutions. The best method of making a soluble casein is by mixing the casein before drying with a concentrated solution of the salt, and then drying the homogeneous mixture *in vacuo*.

At the present day casein is the binder most frequently used in the preparation of distempers and similar water paints. These water paints are rapidly growing in importance. They are capable of application to wood, stone, masonry, roofs, etc., dry regularly and rapidly, giving matte coatings but little affected by rain. Besides being cheap they offer over oil paints many advantages in cases where the preservation of the covered surface is not the main object in view. Very delicate tints may be obtained, the surface covered needs no special preparation and the layer of paint does not close up the pores of the surface.

The popularity of casein as a binder in these paints is based upon the fact that it is soluble in water in the presence of alkalies, and that when the solution is coated on a surface the casein under the influence of the air soon reverts to its insoluble condition.

In the manufacture of these paints commercial casein in powdered form is mixed with a suitable quantity of hydrated lime. The relative amounts of casein and lime must be worked out very carefully. A colour wash containing insufficient casein has no solidity, is not resistant to rubbing or to the action of water. An excess of binder, on the other hand, is not desirable, for not only does it prevent a uniform coating being obtained, but the casein does not all become insolubilised, and frequently cracks and scales off.

(To be continued.)

* From article by Maurice de Keghel in *La Revue des Produits Chimiques*, July 31, 1923.

INDUSTRIAL PITCHES.

THEIR ORIGINS AND CHARACTERISTICS.

By "Latex."

THE term "pitch" has been in use from the earliest times, and the use of pitches of various kinds has been an art employed by man since the dawn of history. It is probable, however, that the word "pitch," frequently met with in Scripture, and other ancient works, refers to the tarry exudations of bitumens of a petroleum nature still found in Palestine, and other countries of the Near East.

To-day, pitches are still very largely used, and find possibly their largest commercial application as waterproofers. The term is now used, however, in a much less general sense, and is really only applicable to the pyrogenous residues resulting from the destructive distillation of a wide range of organic products. Pitches vary very considerably in chemical and physical characteristics, but all have certain physical resemblances. They are all dark-coloured super-cooled liquids, consisting mainly of hydrocarbons.

The Susceptibility Factor and Penetration-Test Curve.

Not only do pitches vary largely from class to class, but specimens of the same class nearly always vary in composition, and such physical properties as melting point, hardness and ductility. Almost the only property which approaches a physical constant, and a means of distinguishing even members of the same class of pitch is the rate at which the consistency of the pitch varies with changes of temperature. As super-cooled liquids, pitches have no sharp transition from solid to liquid when heated, the change being a gradual one. The rate of change is roughly peculiar to each class of pitch, and can be measured by the alteration in hardness experienced through a rise of temperature of one degree. This can be reduced to an exact figure known as the susceptibility factor, which is a ratio between the hardness of a pitch and its melting point, and the estimation of this gives probably the most useful means of identification and works control. Even this factor varies in various members of the same class of pitch, according to, say, the free-carbon content, and the data must be used in conjunction with other chemical characteristics of the pitch. As an alternative the whole change from the solid to liquid form may be plotted on a graph, and the full curve used instead of the susceptibility factor.

This may readily be done by taking the penetration of the sample as a measure of its hardness or consistency. The penetration is the distance a standard needle will penetrate the mass of the sample under standard weight. The penetration test can be conducted at various temperatures between solid and liquid, and the resulting curve has the advantage that it is independent of the amount of oil present in the pitch. Thus, a pitch of any given class which is soft by reason of its distillation not being carried very far gives a similar curve to that given by a harder specimen of the same class.

Another important physical characteristic general to all pitches is the high di-electric value, which renders the pitches of very marked utility in the electrical trades. As a general rule pitches are very poor conductors of heat as well as of electricity, and owing to their fusibility and miscibility with a wide range of organic materials, they can be compounded into a great number of manufactures of unique utility.

Coal-tar Pitches.

Coal-tar pitches constitute the most important type of pitch in use to-day, and are so well known that little need be said here respecting their peculiarities. Generally speaking they are highly weather-proof and acid-proof. They are, however, largely influenced by temperature changes—*i.e.*, they have a high susceptibility factor. Better-known modifications of coal-tar pitch are water-gas-tar pitch and blast furnace pitch. The former is the product of the tar formed from the water gas producer plant, and is very similar to coal-tar pitch, but has an exceedingly fine lustre or gloss, and in addition is very low in "free carbon" content. These characteristics render it attractive for the manufacture of black varnishes.

Blast furnace pitch is the product of very high temperative carbonisation, and is therefore very high in "free carbon." It usually has rather an unattractive appearance owing to a bluish "bloom" which appears on its surface, probably due to high-boiling-point saturated hydrocarbons. It is cheaper than coal-tar pitch, and finds a ready sale for grouting paving blocks, etc.

Wood Pitches.

From very early times wood tars have been used largely in Scandinavia and Russia as crude waterproofers. The pitches derived from wood tars are, however, now in big demand all over the world. The properties are very peculiar, and in composition they bear unmistakable traces of the phenolic bodies found so prolifically in wood tars. The presence of these phenols renders them often readily attacked by water, the phenols being leached out, and the pitch usually assumes a brownish tint, and perished appearance. Wood tars vary however in relation to their source. Many hard wood tar pitches are practically insoluble in all the well-known solvents, but are totally soluble in phenols, and partially soluble in acetone. Coniferous tar pitches are nearly always entirely insoluble in paraffin solvents, but largely soluble in aromatic hydrocarbons. Wood pitches are largely used as caulking compounds for wooden decks and in certain marine paints.

Fatty Acid Pitches.

These comprise the residues from the distillation of stearic acid, wool-grease, etc., and are exceedingly valuable commercial products. While they vary considerably, most samples which come into the market contain considerable quantities of fatty substances, and as a general rule these pitches represent the best available materials for waterproofing compounds. In addition they have usually a very low susceptibility and are very useful as ingredients for baking japans. On exposure or on the usual baking treatment changes occur which render these pitches very resistant and almost insoluble in the usual solvents.

Carbolic and Gutta-percha Pitches.

The pitches obtained from the refining of petroleums are not usually classed as pitches, and their characteristics are so varied that they can hardly be dealt with in an article of this nature. There are, however, a great number of rarer pitches which find their way into the market from time to time, one of which is carbolic pitch. This is a highly-phenolic pitch and is very often used for the manufacture of wood stains (in which case the phenols are an advantage), disinfectants, and also for the manufacture of varnishes toxic to low forms of animal and vegetable life.

Gutta percha pitches are usually "tacky" and soft, but as may be expected, are very elastic and valuable for use in moulded insulation compounds. These pitches are produced in a variety of forms, colour and consistency, and the technology of their composition and use is very limited and little known.

It is well to remember that all pitches retain pronounced traces of their source, and their behaviour can usually be predicted as being similar to that of the parent compound. Recognition of this fact is probably one of the most useful guides in the successful application of this interesting class of material to industry.

ALPHA AND BETA NAPHTHOLS.

A SIMPLE METHOD OF DIFFERENTIATION.

THE use of metallic sodium as a reagent for the rapid and positive differentiation between alpha- and beta-naphthol is described by H. Kunz-Krause (*Chemiker Zeitung*, July 28, 1923). A very small quantity of the naphthol under examination is dissolved in a few ccs. of absolute alcohol, and to the solution metallic sodium (in the form of a thin ribbon) is added so long as reaction takes place. The solution may be cooled with water during the addition of the sodium. In neither case is a precipitate formed, but if alpha-naphthol be present, the solution assumes a bluish-green slightly fluorescent appearance, which on the addition of excess of sodium reverts to its former colourless appearance. In the case of beta-naphthol on the other hand, the solution first assumes a deep blue colour and is strongly fluorescent. Addition of further sodium in this latter case causes colour changes from blue to olive, to brown and finally to brilliant orange, whilst the fluorescence remains unimpaired. According to the discoverer of the test, it is more delicate and safer than any of the methods that have been suggested hitherto.

MENHADEN OIL PRODUCTION.*

THE GROWTH OF AN IMPORTANT INDUSTRY.

THE source of practically all the oil commonly known as fish oil is the menhaden, or moss-bunker, a small, bony, inedible habitant of the coast waters of the Atlantic Ocean from Texas to Maine. These fish originate in the warm waters of the Gulf of Mexico and the Caribbean Sea, travel northward in great schools as the summer progresses and return to the South in winter. The fishing season, following the movement of the schools, begins in April and continues until cold weather sets in.

Historical.

During the early years of the nineteenth century, settlers along the coast made use of these fish as fertiliser by spreading them over the ground and allowing them to rot, but the value of their oil was soon discovered and a means of extracting it devised. It consisted in placing the fish in open boxes, covering them with water and pressing the mass with weighted boards under which disintegration took place and oil was given off. As the oil floated to the surface it was skimmed off in dippers and loaded into larger containers for transportation and further treatment. This process was soon improved by boiling the fish in kettles before subjecting them to pressure, and resulted in a considerable increase in both the quality and quantity of the oil so produced.

The next step was the introduction of the process of cooking by steam under which disintegration was more rapid and the yield of oil was again increased, so that the business of treating fish for the purpose of extracting oil began to assume importance. Plants were established along the Northern coast adjacent to the fishing areas and in 1866 the first of the so-called "floating factories" was built. This plant consisted of a steamer equipped with apparatus for treating the fish as soon as they were taken aboard, and it made possible not only a further improvement in the quality of the oil, but also greatly extended the area over which the fishermen could operate. New land factories were built and new methods devised to get the fish into the cooking kettles before putrefaction, the fishermen soon realising the necessity of cooking and pressing them while they were relatively firm and solid in order to obtain a maximum yield and a satisfactory quality of oil. This expansion of the industry continued normally, until in 1920 there were approximately sixty factories in operation along the Eastern seaboard served by a fleet of 150 steamers and employing perhaps 7,000 men.

The Fishing Operations.

The fishing steamers are of the tug boat type built with a high bow on which the pilot house is placed in order to provide a vantage point from which the sea may be surveyed. Engines and machinery are placed astern, leaving the central portion as an open hold for the handling and storing of fish. The larger steamers have a capacity of 2,000,000 fish, and in addition to their regular equipment carry with them several small skiffs or striker boats used for following the schools after they have been located, and also a larger type of craft called seine boats which serve to carry nets and other paraphernalia to the point of operation. The nets are ordinary purse seines about 2,000 feet long and fifty to sixty feet deep, made of heavy twine of fairly small mesh and fitted with a ring attachment at top and bottom to hold them in place.

The steamers leave their berths in the early morning, spend the day cruising within ten or fifteen miles of the coast and put back to their home factory or into the nearest harbour at dusk. They are limited in range only by the necessity of discharging their cargo promptly, so that the cooking of the fish may be started before they begin to deteriorate. The transfer of the fish from the steamer's hold is accomplished by means of a bucket elevator into which the fish are fed, and carried to a revolving cylinder arranged to weigh or measure the mass before discharging it into the cooking machines.

Extracting the Crude Oil.

The cooking is done in a long cylinder about two feet in diameter, equipped with a screw conveyer that slowly forces the mass through the cylinder, while heat is being applied by means of steam jets in the bottom. This treatment breaks up the fish so that the oil will flow readily when pressure is applied and the soft, wet mass is then conveyed to the presses, which consist of a tapered screw fixed on a hollow shaft rotating inside a similar and parallel shaft called the curb. The mass moves forward and is pressed by the decreasing size of the screw and curb. It is subjected to steam pressure during its travel and drained both internally and externally.

Oil and water are caught in concrete basins beneath the presses and carried to receiving tanks for further treatment, while the remaining solid matter or scrap is deposited separately, dried, treated with acids and sold as fertiliser. Each press has a capacity of 100,000 fish per hour, and in each hundred pounds of material leaving the presses there are approximately four pounds of oil, forty-six pounds of water and fifty pounds of scrap.

The separation of the oil from the water is accomplished by means of a series of open tanks, each connected to take the overflow or skimmings from the preceding tank in the series, so that when the fluid has reached the last tank it is practically free from water. After separation has been accomplished the oil is heated to the boiling point for about thirty minutes, and then, after being allowed to stand for several days, exposed to the rays of the sun, it is run into storage tanks and held ready for shipment to the refiner.

Both the quality and yield of the oil depend primarily on the quality of the fish, which varies with the locality in which the catch is made, the season and the year. The best oil is obtained from the large, fat fish which are found usually in Northern waters towards the end of the fishing season, and a yield of eight gallons of oil per thousand fish is a fair average, though this figure will be exceeded under favourable conditions during the late summer. The quality of the oil also depends on the skill of the handlers at the factory, and the promptness and thoroughness with which the cooking and pressing is accomplished.

During recent years the fishermen have begun to realise the necessity of producing not only as much oil as possible per unit of fish, but also an oil of good quality as determined by its colour, odour, and clearness. This realisation on the part of the producer has resulted in a raising of the standard of their products, and a general improvement in every process in which fish oil is a component. The output of these seaboard factories is the crude oil of commerce, sold and delivered to the refiners in tank cars or barrels, from which it is dumped by them into storage tanks and drawn off as required for further refining.

Refining Menhaden Oil.

The treatment to which the crude oil is subjected by the refiner is a continuation of the process carried on at the fish factory, and consists primarily in heating it to a fairly high temperature and then slowly chilling it in order to allow the solid matter to congeal and separate from the oil. This is accomplished by drawing the oil from the storage tanks into steam-jacketed kettles, where it is heated for a period of about six hours to a temperature of 170°, during which time it is constantly agitated either by air or by mechanical means. This drives out the moisture and dissolves the crystals or foots which have formed in the oil during its stay in the storage tanks.

The oil is then drawn off into cooling boxes or pans and allowed to stand three or four days subject to a gradual reduction in temperature. The cooling is done by means of pipe coils with which the pans are equipped, and through which a circulation of cold water or brine is maintained. As the temperature of the oil falls the foots separate from it and remain in suspension until the oil is ready for filtering.

Filtration may be accomplished in several ways, but the method longest in use consists of straining the oil through a series of canvas bags hung on wooden racks over a group of sheet metal pans. The chilled oil is run by gravity into the bags, through which it drains into the pans below, the foots remaining inside the bags, while the clear oil passes through. Oil so accumulated is the first run of refined oil, and its quality depends on the temperature at which it is strained.

The foots is then removed from the bags, gathered in portable tanks of three or four barrels' capacity and carried to a press, where it is subjected to a pressure of about 3,000 pounds for a period of eight or ten hours, the work usually being done at night, since no labour is required other than an occasional inspection of the gauges. The oil thus separated from the foots is collected in pans beneath the presses, and is known at the refinery as hydraulic oil because of the type of press used. Its quality again depends on the temperature under which it

* From article by Paul T. Bruyere in the *Oil, Paint, and Drug Reporter*.

is pressed, but regardless of this factor it will usually show a few degrees weaker in cold test than the oil obtained from the first straining through the canvas bags. During recent years attempts have been made to separate the oil and foots by centrifugal force, but the result has not been entirely satisfactory. Some foots can be removed in this way, but not enough to leave the oil clear. An oil having a cold test of about 42° F., is the best that has been obtained by the centrifugal method, and in spite of many experiments in this direction the ordinary straining and pressing process continues to stand alone in producing a uniformly reliable, low, cold test oil free from moisture and foreign matter. The oil so obtained should show a cold test of from 30 to 32° F., with other physical properties as indicated in the following tabulation of properties of ordinary winter-pressed menhaden fish oil: —

Free fatty acid	3.64
Saponification value	196.5
Iodine value	188.5
Colour	0.4
Gravity Baume	20.4
Gravity specific	0.9307
Pounds per gallon	7.75
Flash (deg. F.)	515
Fire (deg. F.)	635
Viscosity at 100° F.	128
Viscosity at 210° F.	50
Cold test (deg. F.)	28
Cloud test	34

These tests were determined from a sample of oil worked during the month of November, and slight variations may be expected in oil worked during either colder or warmer weather.

Bleaching and Blowing the Oil.

The refined oil as obtained from the straining and pressing processes is stored in closed tanks, from which it is drawn for blending or for direct delivery to the consumer in tank cars or barrels as required. Certain consumers require particularly light-coloured oil or perhaps a high viscosity, in which cases the pressed oil may be either bleached or blown, or both, to satisfy the demand. Bleaching is accomplished by filtering the oil with fuller's earth or by cooking it with an alkali.

In the fuller's earth process, oil is mixed with the earth and forced through an ordinary horizontal filter press consisting of a series of canvas sheets hung vertically between perforated metal plates, so that the clear oil runs through the perforations into adjacent pans, while the compressed earth and foreign matter adheres to the canvas sheets. This has the effect of lightening the oil several shades in colour, and also clarifying it to a considerable extent.

In the alkali process the oil is mixed with caustic soda, and subjected to heat in an open kettle which produces practically the same results as filtering with fuller's earth, and also tends to cut down the acidity of the oil and to create soap in proportion to the acidity of the oil used. A low acid oil is therefore usually treated by filtration in order to bleach it, and a high acid oil is treated by the alkali process in order to produce soap. In the latter case the resulting bleached oil is separated from the soap by skimming it off the top, and the quality of the oil so bleached is equal in every way to that obtained from the filtration process, but the quantity obtained is considerably less. Oil bleached by either process is sometimes transferred to shallow pans and allowed to stand for several days exposed to heat and to strong rays of sunlight, which treatment clarifies it still further by removing the last traces of moisture and further lightening its colour.

Blown fish oil is obtained by forcing a strong current of compressed air through the oil while it is hot. A special blow tank is used for this purpose, usually a tall tank of relatively small diameter equipped with a steam jacket and with a ventilator arranged in the top. The tank is filled with oil, gradually heated to about 160° F. and agitated by means of a column of compressed air entering through the bottom, the agitation or blowing being maintained until the oil has absorbed enough oxygen to thicken it to the desired gravity or viscosity as the case may be. This treatment increases the acidity of the oil, darkens its colour, partially deodorises it and shrinks its volume.

Utilisation of the Foots.

In one or another of these forms all the refined oil derived from the crude is accounted for, but there is another usable product remaining after the refining of the oil, and that is the foots. Foots is a chemical ingredient of the crude oil appearing as solid matter when chilled, in quantities varying in direct proportion to the temperature at which straining takes place. Approximately 10 per cent. of the crude oil by weight is foots, and it must not only be removed from the oil in order to make the oil commercially valuable, but may itself be refined and used as a base for making soap.

The foots remaining in the hydraulic presses after the oil has been discharged is in the form of a solid cake, dirty brown in colour and granular in structure. This cake is dumped into a kettle and bleached with soda in a manner similar to that followed in bleaching refined oil by the alkali process. The product as it appears in the kettle after treatment is a clear blackish fluid which is drawn off from the top while still hot and filled into barrels. As its temperature falls it congeals into a hard, silky, white substance known as bleached fish foots, or fish stearine, and is used not only in making soap but also as an ingredient of certain kinds of greases.

Cost of Fish Products.

Demand for refined fish oil products in an average year just about equals supply, but both elements are subject to fluctuation. Demand varies with general business conditions as reflected in the manufacturing industries, and supply varies with the weather and other conditions affecting the catch of menhaden during a given fishing season. Owing to these circumstances the price of fish oil products is not altogether a matter of the actual cost of refining them, but is rather a question of whether the fishing season will produce enough fish to satisfy the demand for oil, and the producer's sales price varies accordingly. Similarly, no fixed relation exists between the demand for refined fish oil and the demand for the by-products, foots and soap. The result is that the refiner sometimes finds himself forced to sacrifice foots and soap, although they have been made from high priced oil.

Uses of Menhaden Oil.

Fish oil is largely used in the paint trade in combination with linseed oil and also as a direct substitute for it. Their general characteristics are somewhat similar, but in addition fish oil has a greater tendency to resist heat so that it may be used to advantage in paints for smokestacks, boiler fronts, and other iron work exposed to relatively high temperatures. It often replaces linseed oil in the manufacture of patent leather, printing inks, japans, linoleums, cork flooring and products in which its quick drying and binding qualities are valuable.

During recent years fish oil and foots have been successfully hydrogenated, and chemists are now applying their ingenuity to the problems of converting it into an edible product. With continued efforts in this direction, there is reason to hope that this result will be accomplished before many years have passed.

METHYL ALCOHOL IN ETHYL ALCOHOL.

SIMPLE METHOD OF DETECTION.

PROFESSOR M. R. MEURICE of the Institut Agronomique of Gembloux (Belgium) suggests a method (*Annales de Chimie Analytique*, July 15, 1923) for the detection of methyl alcohol in ethyl alcohol, which has certainly the merit of simplicity although it possesses the limitation of not being sensitive to lower proportions of methyl alcohol than 3 per cent. in the mixture.

Professor Meurice found that if 10 ccs. of ethyl alcohol of 95° were shaken vigorously in a test tube of about 30 ccs. capacity with 10 ccs. of a 20 per cent. aqueous solution of neutral ammonium sulphate, at a temperature of about 18° C. and the mixture then allowed to rest for a couple of minutes, two layers of liquid formed. The lower and least voluminous layer consisted of an almost saturated solution of ammonium sulphate, whilst the upper layer was the alcohol which had become diluted. After standing some time the lower layer became opalescent and finally deposited a few crystals of the sulphate.

When however the above experiment was repeated with ethyl alcohol containing 10 per cent. of methyl alcohol separation into two layers did not take place, but a voluminous precipitate of ammonium-sulphate crystals was formed. With an ethyl alcohol containing only 3.5 per cent. of the lower homologue, the formation of the two layers was not observed, but an abundant crop of crystals was noted. Further experiments showed that, as mentioned above, the reaction was not reliable for amounts of methyl alcohol lower than 3 per cent.

CORRESPONDENCE.

*** We do not hold ourselves responsible for the opinions expressed by our correspondents.*

THE BRITISH CHEMICAL PLANT MANUFACTURERS' ASSOCIATION.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—With regard to your editorial remarks on my speech to the B.C.P.M.A. under the title, "Chemical Plant Manufacturers' Grievances," in the issue of the *Chemical Trade Journal and Chemical Engineer* for August 10, I would suggest that the conclusions you have drawn are hardly warranted from a study of a full report of the speech for the following reasons:—

In the first place, I stated that we should have been housed in the Chemical Section of the British Empire Exhibition, which means that the A.B.C.M. had invited us to join them; but our Association, as an Association, had decided not to show, some of the members being committed to other sections, although some individual members are taking advantage of the opportunity extended to them by the parent Association. Far from the relations between the A.B.C.M. and B.C.P.M.A. "not being closely knit," as is suggested in your note, the relations between these two bodies are most cordial.

In the second place, the two associations being composed of business men, they are, of course, unlikely to attempt to coerce one another. The real inference is "propaganda," as you will see at the end of the paragraph (in the speech) "trading with the members." I shall be glad if you will kindly insert this letter in your next issue to remove any misleading impression, which I am sure you would be unwilling to create.—Yours, etc.,

L. M. G. Fraser,
(Chairman.—The British Chemical Plant Manufacturers' Association).

166, Piccadilly, London, W. 1,
August 20, 1923.

[We are obliged to Mr. Fraser for explaining the true state of the relationship between the A.B.C.M. and the B.C.P.M.A., and are pleased to learn that such relationship is on a most cordial basis. The summary of Mr. Fraser's speech, as circulated to the Technical Press, certainly gave the opposite impression.—*Ed., C.T.J. and C.E.*

BRITISH BARYTES PRODUCTION.

To the Editor of "The Chemical Trade Journal and Chemical Engineer."

Sir,—I have read with much interest your remarks under the heading of "Bleached Barytes" in the issue of the *Chemical Trade Journal and Chemical Engineer* of August 10. It is true there are many large deposits of excellent barytes in this country, and it is somewhat surprising that the bulk of the large quantity that is used in this country is imported.

The principal reason why more is not done to make the country independent of foreign supplies is that the barytes industry is not able to interest capital for development purposes. Prior to the war the greater portion of the barytes used in this country was imported. During the war the supply was, of course, shut out, with the result that the English production of barytes increased tremendously, somewhere round about 80,000 tons being produced per annum, I believe. Immediately after the war, when the barytes industry was in a very prosperous state, there were several schemes afoot for the building of large modern plants for producing from 250 to 300 tons per week.

With the slump in trade, however, and the English barytes market again flooded with Continental barytes (Continental producers having the advantage of the depreciated rate of exchange), the home producer has been very adversely affected, and the result has been somewhat disastrous for the English barytes industry.

The average barytes plant in this country does not operate on a very large scale, and produces about 40—60 tons per week, the bleaching of the barytes being carried out in a coarse state with acid in lead-lined tanks. The barytes is then washed, spread out on a drying floor, and afterwards ground in ball mills and burr stone finishing mills, and in a few cases Raymond and Griffin mills are installed. With the process used and size of plant, the cost per ton for grinding comes out very high when compared with the large plants as operating abroad, which require practically no labour.

The bleaching of barytes and question of extremely fine grinding, as stated in your *Journal*, are more or less simple, and neither operation presents any serious technical difficulty. Since the Armistice I have been actively associated with several schemes for establishing in this country large modern barytes plant, but due to the present state of trade the projects have not advanced. In my opinion, a barytes plant operating in this country on the same scale and process as used abroad would undoubtedly produce, with a good margin of profit, a product of standard quality, and equal, if not superior, to any imported material.—Yours, etc.,

20, Cooper Street, Manchester. L. A. Mitchell.
August 16, 1923

LEGAL INTELLIGENCE.

ESSENTIAL OIL MERCHANTS' FAILURE.

Gerald Bromage and Co., Ltd.

The creditors interested in the voluntary liquidation of the above company, of 9-10, Foster Lane, London, E.C., dealers in essential oils, etc., met on August 17. An approximate statement of affairs was presented, which showed liabilities of £2,680., of which £2,669. was due to unsecured creditors, almost entirely for goods supplied. The assets were estimated to realise £804., or a deficiency as regarded the creditors of £1,876. The stock consisted principally of synthetics, essential oils, spices, and drugs. It was all marketable, although at the moment the prices of such goods were down. The company was formed in June, 1921, with a nominal capital of £5,000., in £1. shares, and took over the business of G. Bromage, which had formerly been carried on at Lower Thames Street. The directors were G. Bromage and F. L. Gibbins. During the period ended June 30, 1922, the turnover was £22,150., with a gross profit of £1,580., but after allowing for all expenses there was a net loss of £1,126. The principal creditors were the Chemische Fabrick Naarden, who were scheduled for over £1,700., and who had recovered judgment for £1,650. The company had acted as agents for the Naarden Co., and had disposed of quantities of goods for them. The present position had been brought about principally, if not entirely, by the slump. He was afraid that there was no question of a reconstruction or of any offer being made.

After a short discussion a resolution was unanimously passed confirming the voluntary liquidation of the company, with Mr. Middleton, of 195, Strand, London, W.C., as liquidator, while an advisory committee of three of the creditors was appointed.

THIRTY-FIVE YEARS AGO.

(From the "Chemical Trade Journal," August 25, 1888.)

Magnesia Cement.—The need of finding some use for the refuse magnesia salts arising as by-products in the manufacture of potash at Stassfurt has caused the subject of magnesia cement again to attract attention. Dr. Grundmann, of Hirschberg, has recently invented a new method of treating the magnesia, for whereas formerly the material was merely calcined, and made up with water, he now carefully slakes the calcined magnesia, and subsequently exposes the compound or casting to the action of carbonic acid gas, much in the same way that builders have been in the habit of drying and hardening plastered rooms by confining the air, and burning coke in them so as to liberate carbonic acid gas. The natural carbonate of magnesia, known as magnesite, is a mineral of great hardness and density, and the similar substance obtained by the above treatment resembles magnesite in its hardness and in its capacity for taking a good polish. Grundmann also employs the magnesia as a cementing agent for various materials, for instance, by the use of marble dust an artificial dolomite is obtained. The magnesia can also be improved by adding to it soluble silicates of the nature of water glass, and it can be used as a stucco for building purposes.

ITEMS OF INTEREST.

Oil in Tasmania.—The Tasmanian Government geologist, says a Reuter's telegram from Hobart, estimates the Tasmanian oil shale reserves situated in five separate fields at 42 million tons, capable of yielding 40 gallons of crude oil per ton, or enough to supply Australia for twenty years.

Transvaal Platinum Discovery.—It is reported that discoveries of platinum have been made in the Waterberg district of the Transvaal. The reef has been traced for thirty miles and samples have been obtained showing 46 per cent. of platinum and payable gold.

Tariff Notes.—A Greek Decree modifies as from July 15 the import duties on the following articles:—Sodium sulphate, sulphide, hyposulphite and hypochloride, chloride of lime, manganese chloride, naphthalene, paraffin wax, stearine candles, paraffin wax candles, specified toilet soaps, quinine, quinidine and cinchona bark.

South Wales Tinplate Amalgamation. — The Grovesend Steel and Tinplate Company, Limited, announce that they have purchased the Duffryn Steel and Tinplate Works, of Morriston, the Mardy Tinplate Works, of Gorseinon, and the Dynevor Tinplate Works, of Pantyffynon. The purchase price, including stocks, will approximate £600,000.

French Iron and Steel Industry.—According to statistics published by the Comité des Forges, the number of blast-furnaces alight in France on July 1 was 106. In the whole country 7 blast-furnaces were relighted during the month of June, of which three were in the East, two in Alsace-Lorraine, one in the South-west and one in the West. The production of pig-iron during June was 447,013 tons, or an increase of 53,585 tons on the production of the preceding month. The production of steel showed an increase of 39,151 tons compared with May, reaching in June a total of 427,600 tons.

Sewage Purification and River Pollution.—At their last meeting the Mersey and Irwell Joint Committee considered some figures which showed that out of twenty-five samples of effluents from manufactories which the chemical adviser had analysed during the last two months four were reckoned fair, four unsatisfactory, and seventeen bad. Of the sixty-eight samples of effluents from the treatment of sewage, eight were good, twenty fair, five unsatisfactory, and thirty-five bad. The chief inspector to the Joint Board has stated that these figures are not representative of the whole watershed. There is no doubt that the work of sewage purification in the Mersey and Irwell district is much more efficiently done now that it used to be.

Fire.—A serious fire occurred on Sunday night at the works of the Shelton Iron, Coal, and Steel Company's works at Etruria, Stoke-on-Trent. It was observed shortly before eight o'clock in the coking and by-products plant and spread with great rapidity. The Hanley Fire Brigade was quickly on the scene, and, assisted by workmen, got the outbreak under control by ten o'clock. By this time the roof of the premises had been almost completely destroyed and considerable damage done to the plant itself. The coking plant was being extended by the company at an estimated cost of £120,000. When completed it would have been one of the largest of its kind in the Midlands for the carbonising of coal and the production of benzol and other by-products on a large scale. The origin of the fire is unknown.

British Standardised Steel Samples.—Standards issued jointly by the Iron and Steel Institute and the National Physical Laboratory, and at present available are No. 1.—Sulphur (S. = 0.027 per cent.). No. 2.— Sulphur (S. = 0.071 per cent.). No. 3.—Phosphorus (P. = 0.029 per cent.). No. 5.—Carbon (C. = 0.65 per cent.). Acid Open-Hearth Steel. No. 6.—Carbon (C. = 0.10 per cent.). Basic Open-Hearth Steel. These samples are supplied, post free, at 21s. per bottle containing 50 grammes, together with certificate of standardisation. They can be obtained, by sending order with remittance, direct from the National Physical Laboratory (Metallurgy Dept.), Teddington, Middlesex, or by post or application from Dr. C. H. Desch, Department of Applied Science, the University, Sheffield; Dr. C. A. Edwards, the University College, Swansea; Colonel E. L. Johnson, Cleveland Technical Institute, Middlesbrough; D. A. MacCullum, West of Scotland Iron and Steel Institute, 93, Hope Street, Glasgow. Other samples are in preparation and will be issued when ready.

Obituary.—It is with regret that we learn of the death on the 26th ult., as the result of a motor accident, of Richard T. Statham, late partner of John Statham and Sons, manufacturers of acid-resisting stoneware.

Canadian Exports of Chemicals.—Exports of chemical products from Canada during the year ended June 30, 1923, amounted to $15,167,316, as compared with the total for the preceding twelve months of $9,540,024.

Low-temperature Carbonisation.—It is reported that Professor Illingworth, of the South Wales School of Mines, has now completely worked out the details of his new process for the low-temperature carbonisation of small coal. It is claimed that the new fuel has proved to be equal to the best Welsh coal for steam raising.

Trade with Morocco. — The Vice-Consul at Casablanca, Morocco (Mr. C. G. Hope Gill), who is now on a visit to the United Kingdom, will be pleased to interview firms interested in trade in Morocco (Tangier and Casablanca districts) at the Department of Overseas Trade during the mornings of August 25 and 27. British firms who desire to take advantage of this opportunity are requested to communicate with the Comptroller-General, 35, Old Queen Street, London, S.W. 1, quoting Ref. 4,879/TG.

Casein Production in U.S.—The output of casein in the U.S. for the year 1922 was 6,907,000lb. This amount was produced by 74 factories. The production for the first quarter of 1923 as reported by 92 factories was 2,037,000lb., while the production for the same quarter of 1922 from 64 factories was 1,166,000lb. This shows that there was a large increase in the production of casein, and in the amount produced per factory, while the number of factories indicates an increase of nearly 50 per cent.

Research in Wool Textiles.—The British Research Association for the Woollen and Worsted Industries announces that for the year 1923-24 Research Fellowships have been granted to Robert Burgess, to carry out investigations on the damage and deterioration caused by bacteria and fungi on woollen goods and yarns during storage, and H. E. Farrar, to conduct research as to the dyeing of wool with acid and mordant colours. Advanced scholarships have been granted to S. Menzer, tenable at the University of Leeds; T. N. T. Graham, tenable at the Scottish Woollen Technical College, Galashiels; P. M. Redman and W. Lee, tenable at the Bradford Technical College.

Atmospheric Pollution Report.—Classified results of investigation into the amount and nature of impurities deposited from the atmosphere at about thirty experimental stations in different parts of the country are given in the eighth annual report of the Advisory Committee on Atmospheric Pollution. Improvements in the form of the standard gauge used in the estimation of suspended matter are described, with particulars of a new and inexpensive gauge now available. A series of experiments to ascertain the direction from which the maximum amount of impurity emanates is recorded, and a description is given of a new portable instrument for the rapid sampling of atmospheric dust, for subsequent microscopic examination and counting of the particles, together wih photo-micrographs magnified up to two thousand diameters.

Mineral Salts in Canada. — The Mines Branch of the Canadian Department of Mines, Ottawa, report the natural occurrence of soluble mineral salts in the provinces of Manitoba, Saskatchewan, Alberta, and British Columbia, either in the form of bedded deposits or as brines. Some are of considerable extent, and are probably of sufficient size to warrant commercial exploitation, provided economical methods of recovery can be developed, and sufficient markets established. The occurrences of these salts may be broadly classed under two types:—(1) Solid salts and brines in undrained or partially drained basins; (2) brines of flowing streams or springs. The composition of the salts occurring in the basins consists chiefly of mixtures of sodium and magnesium sulphates, with, generally, small quantities of sodium chloride, sodium carbonate, calcium carbonate, and calcium sulphate, etc. The brine streams or springs occur in many places, and may carry sufficient salts in solution to warrant their exploitation for medicinal and other purposes. In some of the occurrences the principal salt present is sodium chloride, the other salts being present only in small quantities. The brine springs of northern Manitoba are good examples of this class of deposit

Business Notice.—The goodwill; plant, and stocks of the United Brassfounders and Engineers, Ltd., have been purchased by Hattersley, Ltd.

British Coal Output.—The coal output from the mines of Great Britain during the week ending August 11 (which included Bank Holiday) was 3,566,400 tons, as compared with 5,253,600 tons in the preceding week. The output for the Bank Holiday week last August was 3,623,200 tons.

Unemployment Figures.—The number of persons on August 13 recorded on the live registers of the Employment Exchanges in Great Britain as wholly unemployed was 1,211,900. This week was 20,074 more than in the preceding week, but 273,978 less than the figure recorded on January 1, 1923.

Cement Companies' Merger.—It is reported that negotiations have been concluded for the acquisition of the Humber Portland Cement Company by the British Portland Cement Manufacturers, Ltd. Although details have not been published, it is understood that the Humber Company's shares are being acquired at 30s. each.

Cement Production in China.—A cement manufacturing company, under the name of Chiang Hwa Company, Ltd., is in course of organisation. Works are to be established in Liaoyang, Fengtien. The material for manufacture is obtained from Penlashantze. A capital of 1,000,000dols., to be divided into 100,000 shares of 10dols., is open for subscription.

Magnesium Production in U.S.—The U.S. Tariff Commission has ordered an investigation of costs of production of magnesium with a view to a possible change in rate of duty, as a result of an application by the American Magnesium Co. of Niagara Falls, N.Y., which has asked for an increase in the tariff duty. The corporation is said to be producing magnesium by a new process and at lower cost.

Cupferron for Determination of Uranium.—Cupferron is a complicated hydroxylamine derivative, which has been used largely in determinations of iron. Holladay and Cunningham, of the Union Carbide and Carbon Research Laboratory, presented to the forty-third meeting of the American Electrochemical Society a study of the application of the reagent to uranium determinations. They find that in solutions containing from 4 to 8 per cent. of sulphuric acid, uranium can be quantitatively precipitated in the presence of aluminium, calcium, magnesium, and phosphates. The precipitate is $U(C_6H_5N_2O_2)_4$, which by ignition is converted into U_3O_8.—*Journ. Franklin Inst.*

Silica Deposits of Eastern Canada.—We are informed by the High Commissioner for Canada that the Department of Mines at Ottawa has just published a report on the silica deposits of Eastern Canada. This report, by L. Heber Cole, discusses the occurrence, exploitation, and uses of the silica, and describes in some detail the various deposits in Eastern Canada, including many which, though now undeveloped, may in the future become of considerable industrial importance. The principal markets for silica in Canada are in the large industrial centres of the Dominion, such as Montreal, Toronto, Hamilton, etc. There are many deposits favourably situated in the Provinces of Ontario and Quebec which, if properly operated, should be able to compete readily with similar material which is at present being imported into Canada from the United States.

Glasgow Corporation Chemical Works. — In his fourth annual report on the Glasgow Gas Committee's Chemical Works Department, Mr. W. A. Walmsley (the Manager) states that the result of the year's work has been very satisfactory. The reorganisation and extension scheme, laid down in 1920, is completed; and all new plant has now come into full operation. The prices obtainable for sulphate of ammonia have been considerably better than those realised during the financial year 1921-22. This, coupled with reductions in wages and in cost of raw materials used in manufacture, has resulted in a considerable increase in the net revenue obtained from the ammonia products. Tar and tar products prices for the first three or four months remained fairly stationary. Towards the end of September, owing to shortage, markets became stronger and firmer, and prices steadily advanced. During the last six weeks of the financial year, prices fell somewhat, but they still maintain a fairly high level. After paying all working expenses, etc., the net revenue is £275,568., an increase of £109,948. as compared with last year.

ITALIAN CUSTOMS DUTIES.

MODIFICATIONS AFFECTING THE EXISTING TARIFF.

ACCORDING to an Italian Decree-Law dated July 11 last, provision was made for certain tariff modifications, and these modifications, in so far as they affect the chemical trade, are tabulated below. This table, therefore, shows the amendments made in the General Tariff as established by the Royal Decree of July 9, 1921. The amendments affect, in certain cases, the tariff nomenclature, and also the rates of duty. For the most part, states the Board of Trade *Journal*, from which this table is extracted, the duty alterations are in the nature of reductions of the previous general rates, such reductions being generally effected by reducing the tariff "coefficients." The "coefficient of increase" indicates the figure by which the tariff duty is to be multiplied to determine the amount to be added in order to arrive at the total duty payable; thus a coefficient of 0.5 indicates that the tariff duty is to be increased by 50 per cent.

Tariff No.	Articles.	Import Duty (Gold Lire).	Coefficient of Increase.
		Lire. c.	
669	Bromine ..... 100 kilogs.	2 00	—

REPORTS OF COMPANIES.

Minerals Separation, Ltd.

During the year 1922 the expenditure exceeded income by £18,812. The accounts show that, including a refund of £9,785. for income tax, a credit balance of £12,914. was brought in, which, deduced from the above deficit, leaves a debit balance of £5,899. to be carried forward. The directors state that the year's loss is due to the fact that large plants for the use of the coal cleaning and briquetting processes and of the new ore reduction process are not yet in operation, while the situation as regards the metal industries generally has shown very little improvement. The first plant to use the company's new coal briquetting process has been erected at Nantes, France, by the Compagnie Francaise des Mines Powell Duffryn, and was put into operation last month. The results, it is stated, were excellent. The dividend of the Australian company was increased during the year. It is expected that the results of the working of the company's processes at the Modderfontein Deep Levels, Ltd., will be available before the end of the year. Copper fields are being opened up under the company's supervision in Northern Rhodesia. The results of a trial of the new ore reduction process with ore from these fields are expected during next month.

Calico Printers' Association, Ltd.

The net profit for the year ended June 30 amounted to £800,208., and with £237,371. brought forward, the total to the credit of the profit and loss account is £1,037,579. The directors propose a dividend of 10 per cent. for the year on the ordinary shares, with the addition of a bonus of 2½ per cent. A sum of £150,000. is placed to the general reserve, and a similar sum to the fund for equalising dividends, while £100,000. is added to the employees' benefit fund. The balance to be carried forward is £235,432. The previous accounts covered a period of two years to June 30, 1922, and showed a net profit of £503,542. For the former of these years the dividend on the ordinary shares was 5 per cent., while for the latter it was 7½ per cent., and a sum of £50,000. was added to employees' benefit fund.

Virginia Carolina Chemical Company.

Accounts to May 31 show net loss, after providing for depreciation, bond interest, and guaranteed dividend of 7 per cent. on consumers' chemical corporation preferred stock, of 2,894,326 dollars. Surplus brought forward was 6,295,449 dollars; add 15,741,225 dollars arising from reduction of valuation of common capital stock. After deducting loss, a special provision of 2,400,000 dollars for doubtful accounts, 5,059,608 dollars cost of retirement of old bonds, and cost of new issues, and 226,034 dollars miscellaneous adjustments, surplus stands at 11,456,704 dollars.

B. Laporte, Ltd.

The net profit for the year ended June 30 was £20,714. (against £17,586. for the preceding year), while £3,975. was brought forward. It is proposed to write £441. off goodwill account, to transfer £2,000. (against £1,000.) to bad debts reserve, and to pay a dividend on the ordinary shares at the rate of 11 per cent. per annum, less tax (against 10 per cent.), a balance of £10,038. being carried forward. A sum of £5,847. has been recovered in respect of E.P.D. This has been placed to taxes suspense account, which, after charging amounts paid for income-tax and corporation profits tax, shows a balance of £10,547. During the year £17,933. has been expended on additional plant and buildings.

DIVIDENDS.

The Mint, Birmingham.—Directors have resolved to declare an interim dividend at the rate of 6 per cent. per annum, less tax, on the preference shares for the six months ending September 30, 1923.

United Indigo and Chemical Company, Ltd.—Dividend at the rate of 5 per cent. per annum, less tax, for the six months ended June 30 on the ordinary shares, together with a further dividend of 10 per cent., less tax, on the ordinary shares, making 15 per cent. for the year (against 12½ per cent. for the preceding year. A further dividend is also declared of 10 per cent., less tax, on the preference shares, making 15 per cent. for the year (against 12½ per cent. for the preceding year).

J. Mandleberg and Co., Ltd.—The directors have declared an interim dividend of 1s. per share, less tax.

International Paint and Compositions Company, Ltd.—Interim dividend of 3 per cent. on the preference shares, but no interim dividend will be paid on the ordinary.

TRADE INQUIRIES.

The following inquiries have been received at the Department of Overseas Trade (Development and Intelligence), 35, Old Queen Street, London, S.W. 1, whence, unless otherwise stated, further information may be obtained:—

British West Indies.

An important firm of commission merchants in Trinidad desire to secure the representation of British manufacturers of cement. (Ref. No. 183.)

Canada.

H.M. Trade Commissioner at Winnipeg reports that a firm in Manitoba, Canada, desire to be placed in touch with British manufacturers of school chalks and crayons. (Ref. D.O.T. 11735/E.D./M.C./A/2.)

Bulgaria.

A firm of agents and importers in Sofia desire to enter into business relations with firms dealing in oil, varnish, lead, zinc and black sheets. (Ref. No. 191.)

Finland.

A firm of commission agents in Helsingfors desire to secure the representation for Finland of British exporters of vegetable oils. (Ref. No. 192.)

Norway.

A commission agent in Christiania desires to secure the representation for Norway of British exporters of cocoanut oil, copra ground nuts, refined ground nut oil and crude and refined glycerine. (Ref. No. 196.)

Algeria.

A merchant and commission agent in Bone, Algeria, desires to obtain representation of a British firm for the importation of copper sulphate, sulphur and fertilisers, and for exportation of all Algerian products. Correspondence in French. (Ref. No. 207.)

NEW COMPANIES.

Burlington Syndicate, Ltd.—Private company. Capital £100. Manufacturing and research chemists, etc. Office: 4, Great St. Thomas Apostle, London, E.C.

Carr and Day and Martin, Ltd.—Private company. Capital £50,000., £1. shares (10,000 7½ per cent. cumulative participating preference and 40,000 ordinary). Manufacturers of boot and other polishes, etc. Office: Brunswick Park Road, New Southgate.

E. Miller and Co. (Peckham), Ltd.—Private company. Capital £2,500. Tanners, dressers, dyers, etc. Office: Clifton Leather Works, King Arthur Street, Peckham, London, S.E. 15.

J. M. Smith and Co. (London), Ltd.—Private company. Capital £10,000. Chemical manufacturers. Office: Hampton Chemical Works, Arthur Street, Old Kent Road, London, S.E.

Osmos Salts, Ltd.—Private company. Capital £6,000. Manufacturers of and dealers in medicinal salts, drugs, chemicals, etc. Office: Thanet House, 231, Strand, London, W.C

Phœnix Glass Company, Ltd.—Private company. Capital £1,000. Office: 24, Christmas Street, Bristol.

W. R. Smith and Sons, Ltd.—Private company. Capital £25,000 Manufacturers of materials and specialities from animal, vegetable, and chemical products. Office: Tattenhall Road Works, near Chester.

Wilson Chemical Company (Leeds), Ltd. — Private company. August 7. Capital £1,000. Chemical manufacturers. Office: The Old Parrott Yard, The Calls, Leeds.

FERTILISER NEWS.

Nitrate of Soda.—The market for the Chilean product continues disappointing; sales by the Producers' Association amounting during the first half of the current month to about 3,000 tons only. This material was taken at the official price of 20s. 7d. per metric quintal, but some activity has been noticeable in the resale market at 20s. 5d. Both in the United States and in Europe an easier tendency is in evidence. In the former market, cotton planters and agriculturists are waiting to see some financial return for their produce before committing themselves to fertiliser orders, while there is a general feeling that nitrate prices will decline later in the autumn. On the Continent, however, the nitrate market is dominated by the political situation. Stocks in European ports are low; consequently shipments are fairly well maintained at 52,000 tons to Europe, 35,000 tons to the United States, and 8,000 tons to other countries, making a total of 95,000 tons for the first half of August. Actual arrivals amounted to about 74,000 tons. Deliveries from ports at 17,500 tons were rather better than for the corresponding period of last year, and left port stocks at about 102,000 tons on the 15th inst., which, with 164,000 tons afloat for this market, makes the visible supply for Europe (including Egypt) about 266,000 tons, compared with 258,000 tons at the same date in 1922. Contrary to anticipation, production during July showed a decrease on the June figure, the cabled corrections stating that the total for last month did not reach more than 157,000 tons, compared with 166,000 tons in the previous month. Stocks in Chile, therefore, based on export and production figures, are being slowly decreased, thus making the position of the fertiliser more stable at the moment. The danger in this ultra-conservative attitude is, however, that consumers will not readily forget the high prices they are having to pay during the present depressed state of agriculture generally, accompanied as it is by the shortage in nitrogenous fertilisers.

Sulphate of Ammonia.—The present inquiry for this fertiliser on home account is not of much volume, farmers being too occupied with harvesting operations to consider the question of orders. The holiday season also adds dulness to the market position, but it is possible that the demand later on will be rather better if the promising estimates of the current harvest are fulfilled. The general outlook so far as sulphate is concerned is rather uncertain, although it is satisfactory to learn that the dock strike has ended at London and work is proceeding at that port. Inquiry for export is still good, and British producers are certainly alive to the position. Prices are being shaded to ensure the absorption of all the sulphate now being made—a policy which results in production being kept up to the maximum, with the natural result that overhead charges are reduced. It seems fairly certain that there is a market for all the sulphate that is being made, though there appears to be an idea current in this country that prices will be lower towards the end of the year. In view of the decreasing activity in the iron and steel industries—16 furnaces went out of blast during July,—it is surmised that the production of sulphate of ammonia will diminish through the coming months. It would therefore seem to be wise for dealers and consumers to order early, in order to take advantage of the Federation's offer of sulphate at £14. 10s. per ton during September for neutral material showing 25¾ per cent. ammonia. With regard to the position on the other side of the Atlantic, some little material has been available for export orders, but, apart from Japan, there has been little further business done. Exports of sulphate from the United States amounted to 15,670 tons in April last, bringing the total for the ten months ended April 30 to 107,290 tons.

Position of British Agriculture.—In view of the serious economic position of the superphosphate industry in this country, it is disappointing to learn that the past twelve months have witnessed a considerable further decrease in the acreage of arable land in England and Wales. A preliminary tabulation of returns collected by the Ministry of Agriculture in June last shows a reduction of 85,000 acres in the total area of crops and grass, as compared with the figure recorded for 1922, the acreage this year being 25,941,000; but when an analysis is made it is found that the arable area has fallen by no less than 129,000 acres, while permanent grass land shows an increase of 44,000 acres. The decrease in the arable area is mainly accounted for by the corn, pulse, and potato crops, and is a significant proof of the critical period through which the agricultural industry has been passing, especially as a further analysis reveals a reduction of 458,000 acres in the total under the three chief cereals, including mixed corn, wheat having declined by 226,000 acres, barley by 35,000 acres, and oats by 190,000 acres. The area of wheat is the lowest since 1913, the barley area is, with one exception (1915), the lowest on record, and the area of oats is practically the same as in 1913. Figures concerning root crops, however, afford some satisfaction. Turnips and swedes are 40,000 acres more than last year, and sugar beet, for the growing of which every encouragement is being given, with 17,000 acres, is more than double the area of 1922.

China's Requirements of Fertilisers.—The use of fertilisers in South China has shown a marked increase in the past few years. During 1922 the imports of these products into Hongkong amounted to 15,410 tons, as compared with 3,612 tons for 1921, and 2,308 tons for 1920. Until 1922 Great Britain and Japan were the principal sources of supply, about 40 and 25 per cent. respectively coming from these markets, while the United States ranked third in importance, furnishing an average of 14 per cent. of the total annual importation. During the past 12 months, however, this situation has gradually changed. American manufacturers have succeeded in obtaining almost 35 per cent. of the business done in 1922, as compared with 28 per cent. secured by British manufacturers and 24 per cent. by Japanese. Of the total of 15,410 tons of fertilisers imported into Hong Kong during 1922, the United States supplied 5,773 tons, United Kingdom 4,097 tons, Japan 3,800 tons, North China 1,359 tons, Canada 255 tons, South America 100 tons, and other countries 26 tons. The fertiliser most in demand is sulphate of ammonia, which at the beginning of June realised an average price of £22. per ton. Hong Kong being a free port, there is no duty on fertilisers, but on imports of these materials into the Republic of China an *ad valorem* duty of 5 per cent. is charged.

New Japanese Fertiliser. — The use of a new fertilising material, known as "promoloid," and consisting chiefly of colloidal magnesium silicate, is claimed by Japanese manufacturers to accelerate the growth of vegetables. It is well known that the Japanese islands are of volcanic origin, and it was observed, state the makers of the new product, that certain districts were noted for the early production and superior qualities of vegetables. An investigation proved that a constituent of the soil common to all these favoured areas was colloidal magnesium silicate, and experiments were made with the material with a view to establishing its responsibility for the increased crop yields. The preparation which has now been brought out under the name of "promoloid" is sold in liquid form, and, after having been subjected to field tests, is said to have proved of distinct value in increasing the yield and quality of crops. Particulars as to cost of production and the economic possibilities are not forthcoming, but further information on these points will be of interest.

Australian Superphosphate Industry.—In view of the country party's agitation for cheaper superphosphates, the Australian Commonwealth Government has introduced a Bill to remove the sulphur duty, approximating 85 per cent., and to substitute a bounty of 45s. a ton on sulphuric acid obtained from pyrites manufactured within the Commonwealth. This bounty, costing £100,000. yearly, will adequately protect the Mount Lyell works and the projected electrolytic zinc works. It is specially provided that if the bounty is removed the duty will be automatically restored.

IMPORTS OF CHEMICALS AND ALLIED PRODUCTS IN JULY.

(Concluded from page 198.)

THE following returns, which are taken from the import statistics of the United Kingdom, give the amount and value of chemicals and allied products imported during the month of July, 1923, compared with 1921 and 1922. As from April 1, 1923, the import trade of the Irish Free State is excluded from the Returns.

Platinum Production in the U.S.—Of the 968 ounces of crude platinum produced in the United States in 1922, the U.S. Geological Survey finds that Alaska yielded 39 ounces, California 876 ounces, and Oregon 53 ounces. the product sold for 195,000dols. The year's total purchases of crude platinum by refiners amounted to 67,570 ounces, of which 53,385 ounces came from Colombia, 10,085 ounces from Russia, and 12 ounces from Canada.

EXPORTS OF CHEMICALS AND ALLIED PRODUCTS IN JULY.

(Concluded from page 199.)

THE following returns, which are taken from the export statistics of the United Kingdom, give the amount and value of chemicals and allied products exported during July, 1923, compared with 1921 and 1922. As from April 1, 1923, export trade of the Irish Free State is excluded from the Returns.

CUMBERLAND COKING AND BY-PRODUCT INDUSTRIES.

[Specially Contributed.]

The brisk demand for coke remains the best feature of an otherwise gloomy situation. The iron and steel trades are depressed, and the coal trade also is now slack. Rock bottom, however, appears at last to have been touched. There is certainly little apprehension felt as to any further decrease in the demand for the class of iron in the smelting of which the local coke is employed. It is quite true that the Continent is no longer an important consumer, but there is a heavy tonnage of iron going to the Midlands, and the expectations are that the district will continue to absorb considerable supplies for some months to come. In that case, of course, the seven furnaces in blast at Workington will remain in operation, and it is not beyond the bounds of possibility that in the autumn another furnace may be lighted in West Cumberland. Coke is in sharp request, and, indeed, there is not enough to go round now that the Continent is in the market. The West Cumberland and Furness district furnaces have all been short at times. Local smelters are paying from 29s. to 33s. per ton, according to carbon content. The Continent is paying from 34s. to 38s. per ton, f.o.b. Residuals are in fair demand. The entire make of tar is being absorbed by the chemical works on the coast. Crude benzol is rather on the easy side. Sulphate of ammonia is being exported to the Canary Isles, and there is very little being stocked, except when deliveries are difficult to arrange. Chemical products are rather slow. Road tar is dull, and solvent naphthas are not brisk. Sulphuric acid is a fairly good trade. East Coast coke supplies this week are 8,200 tons.

It is stated that a settlement is in sight at the Whitehaven collieries. An offer has been made which may be accepted by the representatives of both sides. It will remain, of course, for the miners to ballot on any propsals submitted to them.

SOUTH WALES NOTES.

[Specially Contributed.]

Business in the tinplate trade remains rather dull, new orders not being booked for any large quantities. The Far Eastern markets are now the chief consumers. There was a falling off in the exports last month of 1,000 tons as compared with July, 1922; but on the basis of seven months' trading an increase of 60,000 tons is shown on comparison with last year. During the week an important deal took place when the proprietors of the Grovesend Steel and Tinplate Company, Ltd., acquired the controlling powers of the Duffryn Steel and Tinplate Works, Morriston; the Mardy Tinplate Factory, Gorseinon; and the Dynevor Tinplate Company's undertakings. The acquisition of these important industrial concerns make the Grovesend Company the largest producers of tin and block sheets in the United Kingdom. Business in the galvanised sheet trade is improving, several new orders having been placed. There is also a better inquiry for patent fuel, but as quotations are not so firm, orders for large quantities are lacking. Owing to the abundance of small coals, manufacturers are accepting lower prices, and business for immediate delivery is much better. The chief export markets at present are Spain and France. Cokes have been somewhat neglected, though the outputs of the ovens have not diminished. Seeing that the by-produtcs, on the whole, are selling fairly well, the probability is that coke prices will be still further reduced. There is no improvement in the copper industry, and at present not more than 25 per cent. of the workers are fully employed. The nickel factories, on the other hand, are steadily working. The chemical trade is rather weak in tone.

Included in the week's imports were 97cwt. white lead from Bremen, 42 tons calcium carbide from Sarpsborg, to Cardiff; 1,870cwt. nickel oxide from Montreal, 600cwt. calcium carbide from Amsterdam, 2,800 tons bauxite from Bombay, 1,000kilo. calcium carbide from Hamburg, 2 tons tin oxide from Rotterdam, 800cwt. magnesite from Hamburg, to Swansea; 635 tons of iron pyrites from Huelva to Llanelly. Exports included 5 tons chloride of lime from Newport to Hennebont.

GAZETTE NEWS.

MORTGAGES AND CHARGES.

Bede Metal and Chemical Company, Ltd., Hebburn-on-Tyne.—Registered July 31. £60,000. debs. (inclusive of £50,000. already registered) (filed under sec. 93 (3) of the Companies (Consolidation) Act, 1908), present issue £10,000.

Brown (E) and Son (Blacking and Boot Polish Manufacturers), Ltd., London, E.—Registered August 2, £10,600. mort., to E. P. Wilson, 61, Wool Exchange, London, E.C., and others.

Hewett and Reynolds, Ltd., London, N.W., dyers.—Registered August 2, £1,000. mort., to E. J. Hewett, 104, Valkyrie Road, Westcliffe-on-Sea.

Produce and Chemical Company, Ltd., London, E.C.—Registered August 7, £600. deb. and £400. deb., to Mrs. E. E. Anderson, 46, Brunswick Square, Hove.

Randall (F.) (Luton), Ltd., bleachers, etc.—Registered July 31, £1,000. deb., to Mrs. E. M. Randall, 83, Hazelbury Crescent, Luton.

Richardson (R. J.) and Co. (London), Ltd., London, E.C., ebonite manufacturers, etc.—Registered August 2, £250. debs.

Synthetic Products Company, Ltd., London, E.C.—Registered July 31, £1,000. charge, to Research Syndicate, Ltd., 50, City Road, London, E.C.

SATISFACTIONS.

Taylors' Drug Company, Ltd., Leeds.—Satisfaction registered August 3, £700., registered June 11, 1911.

BANKRUPTCY INFORMATION.

Curtis, Wm. Hy., Atlas Chemical Works-cot and trading at Atlas Chemical Works, Newmills, as W. H. Curtis and Co., manufacturing chemist. R.O., August 10. Adjourned August 10.

Heyl, Geo. E., King's-ho., Kingsway, London, W.C. July 4. Order of discharge, May 4, 1923, varied and in lieu thereof, bankrupt discharged subject to consent to judgment for £200. Note.—£100, a first instalment to be paid prior to signing of order, since paid.

LIMITED COMPANIES. — Appointments of Receivers; Resolutions and Notices as to Winding-up; Petitions; Orders; and Official and Other Notices.

Central Chili Copper Company, Ltd.—Resolved August 3: That the company be wound up voluntarily. F. T. Whinney, of Whinney, Smith and Whinney, liquidator.

Land Fertilisers, Ltd., Tadcaster.—Resolved July 4, confirmed July 30: That the company be wound up voluntarily. W. Carr, 27, Regent Street, Barnsley, liquidator.

Barron (Thomas), Ltd., Mexborough, bottle manufacturers.—W. H. Copley, of Hart Moss and Co., Rotherham, appointed liquidator August 3.

DISSOLUTION OF PARTNERSHIP.

(*Note.—When two dates are given in the following announcements, the first is the date of the dissolution. The date in parentheses is that of the official advertisement.*)

Stanford, Wylie and Fraser (Jno. Fraser and Alex. Wylie, jun.), Argyle Oil Mills and Chemical Works, Possilpark, Glasgow, oil refiners and merchants. June 15, by death of J. Fraser. Debts by A. Wylie, jun., who continues.

COUNTY COURTS' JUDGMENTS.

(The following returns are taken from the Registry of County Courts' Judgments. Publication does not imply inability to pay. Many Judgments may have been settled between the parties, or paid. Judgments settled otherwise than through the Court may appear unless "Satisfaction" is entered up within twenty-one days from Judgment. Registered Judgments are not necessarily for debts. They may be for damages or otherwise, or they may be against defendants liable in a representative capacity, and not personally. Judgments are not returned to Registry if satisfied in Court Books within twenty-one days.)

Blunt, W. H., and Son, 70, Snow Hill, Birmingham; manufacturing chemists; £18. 12s., June 22; £13. 17s. 2d., July 2.

Rathbone and Orlans, Ltd., 52A, Drury Buildings, Drury Lane, Liverpool; chemists; £14. 0s. 5d., June 28.

Beresford, Thos. G., Grant Street, Leeds Road, Bradford [illegible] Soap Company); soap manufacturer;

201,940 and **201,941**

ABSTRACTS OF LATEST COMPLETE SPECIFICATIONS.

Explosives. T. Hawkins, Slatington, Pennsylvania, U.S.A. British Patent. **199,489**, of 1922.

An explosive is prepared by treating mercury with a mixture of nitric and sulphuric acids then with denatured alcohol or ether ethyl alcohol, the precipitate being washed

and dried free of acid. To the above, may be added another material prepared as follows: Picric acid dissolved in water is treated with litharge or another oxide of lead, preferably while the solution is kept boiling; to the solution, after filtration, is added a solution of potassium chlorate, or potassium nitrate. A paste results and is separated by filtration, pressure, or suction and dried. The dry product may be treated with fuming nitric acid and again treated with litharge, etc., as above. Other explosive compounds may be added with the dried product to the mercury compound referred to above.

Purifying Salt. J. T. Westermann, Bussum, Holland. British Patent, **199,607**, of 1922.

Brine is purified by adding a reagent consisting of two molecular proportions of disodium phosphate to one of sodium carbonate so as to remove calcium and magnesium as phosphate and then barium chloride to remove the sodium sulphate. The reagents are preferably added while the solution is boiling with agitation. The mixed precipitate of phosphates and barium sulphate may be used as a white pigment, or the phosphates may be used to make di-sodium phosphate and the barium sulphate be used as a pigment. The purified brine may be evaporated to complete dryness. When the salt is to be used for certain purposes, such as the production of sodium sulphate, silicate, or phosphate, the treatment with barium chloride may be omitted.

Compositions for Removing Paint. H. Hamaguchi, Osaka, Japan. British Patent, **199,504**, of 1922.

A pasty composition for removing dried paint comprises an alkaline aluminate, caustic alkali, and rice bran. In an example, 3 parts by weight of a 10 per cent. solution of ammonia are added to 2 parts by weight of a 35 per cent. solution of aluminium sulphate and the precipitated hydroxide dissolved by the addition of caustic soda or potash; 90 per cent. by weight of this solution is added to 10 per cent. of a mixture obtained by mixing a 10 per cent. solution of caustic potash with half its own weight of rice bran. If the aluminium hydroxide has been dissolved in excess of alkali, the rice bran may be added directly to the solution. The composition is applied to the paint by brush or blowing nozzle, and after an interval, the whole is washed off with water.

Fixation of Nitrogen. V. Gerber, Zürich, Switzerland. British Patent, **199,667**, of 1922.

A mixture of aluminiferous material such as clay, bauxite or alunite and an alkaline earth compound such as barium or calcium oxide, hydroxide, carbonate or sulphate in considerable quantity together with iron or an iron ore and with or without fluxes such as alkaline earth chlorides, fluorides or carbides or sodium chloride, is fused in an electric furnace and the product after cooling and grinding is heated in nitrogen, with or without pressure, the reaction being exothermic. The fusion process produces a mixture of carbides and alkaline earth aluminate which readily separates from the ferrosilicon produced from the iron and the reduced silica. The nitrogenised product is treated with water or with a solution of for instance alkali hydrate carbonate or sulphate with or without pressure to obtain ammonia and aluminate and regenerate the alkaline earth compound employed. The aluminous material and the alkaline earth compound employed may be calcined prior to the fusion so as to remove volatile matter such as carbon dioxide, sulphur dioxide, and alkalies.

Sulphur Dioxide Refrigerators. F. W. Golby, London. (Utility Compressor Co., Detroit, Michigan, U.S.A.) British Patent, **198,770**, of 1922.

In compression machines employing sulphur dioxide, the circulating-system is washed out with carbon dioxide previously to charging it with the sulphur dioxide, to minimise corrosion. The system may be dried and charged with carbon dioxide at about fifty pounds pressure and exhausted, this step being repeated as desired, the sulphur dioxide being charged after the last exhaustion; or the system may be filled with carbon dioxide at about atmospheric pressure before charging it with the sulphur dioxide.

Refractory Substances. C. S. Garnett, W. A. Reid, F. E. S. Greenwood, and F. S. Cowlishaw, all in Derby. British Patent, **197,791**, of 1922.

Dolomite or magnesian limestone is partly calcined so that the product contains 8-12 per cent. of carbon dioxide; to the calcined material, mineral substances, such as silicates or oxides, which prevent hydration, are added, and the mixture is made plastic with water, moulded into bricks, etc., either before or after slaking is completed, and fired at about 1,500° C. Suitable substances for preventing hydration are olivine, talc, serpentine, kaolin, chlorites, bauxite, felspar such as labradorite and orthoclase, oxides of iron and titanium such as ilmentite, and pyroxenes, such as diallage and other augites.

ABSTRACTS OF LATEST SPECIFICATIONS OPEN TO PUBLIC INSPECTION BEFORE ACCEPTANCE.

Aluminates. J. Koritschoner, Vienna; and F. Hansgirg, Steeg, near Goisern, Austria. British Patent, **199,017**. Convention date, June 9, 1922.

Aluminiferous materials such as bauxite are mixed with alkaline earth compounds such as lime and with carbon in certain proportions and fused in an electric or other furnace. The product is cooled and powdered, and is leached with a solution of an alkali such as sodium carbonate to obtain alkali aluminate. The leaching may be effected at 100° C. The proportion of alumina to lime may be 47.5 to 52.5 and the quantities given in an example are 64.9 parts bauxite, 36.9 parts lime, and 10 parts charcoal. It is stated that metallurgical processes, especially the production of iron in blast or electric furnaces, may be carried on so that the slag contains lime and alumina in the above proportions so that the alumina may be extracted from the slag as above described.

Catalytic Materials. C. Urfer, Geneva. British Patent, **199,025**. Convention date, June 12, 1922.

Catalytic materials for use more particularly in the synthesis of ammonia are produced by heating an alkaline earth metal or lithium in the compact state in the presence of a gas, such as ammonia or hydrogen, with which it will combine to form a dissociable compound, mixing the compound with an inert oxide such as lime or magnesia, heating the mixture *in vacuo*, and finally allowing it to cool in an atmosphere of nitrogen. The product contains the nitride of the metal in a finely divided state. By omitting the step of cooling in nitrogen, the metal is obtained as a fine powder mixed with inert oxide. The addition of the inert oxide prevents the powdered metals from fusing and agglomerating during the heating process. According to the example, commercial lithium is heated in pure, dry ammonia, the resulting amide mixed with powdered lime or magnesia, heated *in vacuo*, and then cooled in a current of nitrogen. If the alkaline earth metal or lithium be heated in hydrogen, the corresponding hydride is formed and may be treated in the same way as the lithium amide. It is stated that the synthesis of ammonia can be effected at atmospheric pressure or low pressures by using the products as the catalytic materials.

Tanning Agents. M. Melamid, Freiburg, Baden, Germany. British Patent, **194,723**. Convention date, March 11, 1922.

An artificial tanning material is obtained by esterifying waste sulphite liquor by any method, but preferably with sulpho-chlorides. The products may be used alone or in admixture with other natural or artificial tanning substances. According to the example, a mixture of waste sulphite liquor and caustic soda is heated with toluene sulphochloride.

Rubber Vulcanisation Accelerators. Naugatuck Chemical Company, Naugatuck, Connecticut, U.S.A. (Assignees of H. S. Adams and L. Meuser, Naugatuck, Connecticut, U.S.A.) British Patent, **199,354**. Convention date, June 19, 1922.

Disubstituted guanidines are obtained by treating a symmetrically disubstituted thiourea with ammonia and a metallic compound, such as zinc oxide, lead oxide or lead carbonate, capable of eliminating the sulphur from the thiourea. According to the example, *sym*-diphenylurea is heated with zinc oxide and strong aqueous ammonia, each in excess, to a temperature not exceeding 80° C. The resulting mixture of diphenylguanidine, zinc sulphide and zinc oxide,

may, after filtration and drying, be used directly as a vulcanisation accelerator; or the diphenylguanidine may be separated by boiling the mixture with hydrochloric or other acid, neutralising the excess of acid with sodium acetate or similar salt, introducing hydrogen sulphide to precipitate the zinc, filtering, and finally liberating the diphenylguanidine from its salt by means of alkali. If lead oxide be used instead of zinc oxide, the reaction product is digested with sulphuric acid and the diphenylguanidine sulphate solution filtered off.

MARKET REPORTS.

LONDON "OPEN MARKET" REPORT. Wednesday.

It is recognised that in many cases the prices quoted show little relation to makers' prices to domestic consumers on contract. They will, however, serve as a useful indication of current values on the open market for spot supplies. Attention is drawn to the fact that the British Chemical and Dyestuffs Traders' Association, whose Secretary compiles this report, is prohibited from trading or profit-making in any form; consequently, the market information given may be taken as impartial and unbiassed. Prices quoted ex wharf, except where otherwise stated.

Industrial Chemicals.—There has, perhaps, been a little more inquiry on the market of late, but business is still far from good, and continues to be limited to small quantities. The dock strike, which seems to have ended at last, has made things exceedingly difficult both as regards imports and exports. With a settlement of the political situation on the Continent, we may look for something in the way of an all-round improvement and steadier conditions generally. **Acetic Acid,** 80% technical, about £47.; 80% pure, about £51.; 98% glacial, £73. in glass demijohns and £60. in casks; spot stocks are still very restricted, and at the prices quoted the market appears to be very firm. **Acetone,** British Government specification, £125. to £127. per ton, in drums; the spot position remains exceedingly strong, with little or no supplies available to meet the good inquiry; higher prices are expected in the near future. **Alum,** lump, in casks, £10. to £10. 10s. per ton; dealers are offering at these rates, but business remains rather poor. **Arsenic,** Cornish white powdered, on spot, £73. to £74. per ton; these high rates are maintained for spot goods, but cheaper prices are mentioned for forward delivery. **Anhydrous Ammonia,** 99.95%, about 1s. 5d. per lb.; the market keeps steady at this level, but there has not been much doing of late. **Barium Chloride,** 98—100%, about £15. to £15. 5s. per ton; dealers are offering on spot at about these figures, with only small business doing. **Bleaching Powder,** 35—37%, £10. to £10. 10s. per ton; the demand for this product so far as dealers are concerned remains quiet. **Borax,** commercial, granulated £26. 10s., crystals £27., powdered £28., extra fine £29.; B.P., crystals £31., powdered £32., extra fine £33. per ton, for home trade only, in 2cwt. free bags, carriage paid to destination. British makers' prices continue at these unchanged rates; quotations for export vary as to destination; dealers are offering for home consumption under similar conditions to makers at: granulated £25. 10s., and powdered £27. per ton. **Borax Glass,** lump, £74.; powdered, £75. per ton, in tin-lined cases; British makers' prices, for home trade only, are unaltered at these rates, packages free, carriage paid to destination. **Boric Acid,** commercial, crystals £50., powdered £52.; B.P., crystals £56. powdered £60., extra fine £62. per ton, in free bags, carriage paid to destination; British makers quoting at these unaltered rates for home trade only; dealers are offering some grades at competitive prices. **Cream of Tartar,** 99—100%, 90s. to 92s. 6d. per cwt., less 2½%; this article seems to be firmer, and tends to move to slightly higher rates. **Citric Acid,** B.P., crystals, about 1s. 6d. per lb., less 5%; this market seems to have moved to still lower prices for spot goods, and remains weak; large parcels could no doubt be obtained for less. **Epsom Salts,** commercial quality, about £5. per ton, in bags; dealers are finding little demand for the spot material floating about. **Formaldehyde,** 40% volume, spot, about £95. per ton, and forward about £75. per ton; the Referee's decision removing the import duty of 33⅓% has had the immediate effect of lowering the price of this article for forward delivery; business is likely to be good after the prolonged hold-up. **Glauber's Salt,** commercial quality, £3. 15s. to £4. per ton, in bags; there is still but small inquiry on spot for this article. **Lead Acetate,** brown, about £41. to £42.; white, about £42. to £43. per ton; supplies on spot are scarce, and Continental offerings are dear and limited. **Litharge,** about £35. 10s. to £36. per ton; dealers are offering Continental material at about these figures, and some moderate business has been booked. **Lithopone,** 30% Continental red seal, £22. to £22. 10s. per ton; the demand on spot has dropped off a little, but prices keep very steady both on spot and on the Continent. **Ammonium Chloride,** grey galvanising, £30. 10s. to £31. per ton; this market keeps fairly steady, and there has been a moderate business passing. **Nickel Sulphate,** home trade, single and double salts, £38. per ton, delivered; export, single and double salts, £38. per ton, f.o.b.; British makers continue to quote at about these rates. **Oxalic Acid,** about 6d. per lb.; there is no change in the quoted price of this article; business remains very slow. **Carbonate of Potash,** 90—92%, about £27. 10s. to £28.; 96—98%, about £31. to £32. per ton; offerings on spot appear to vary somewhat, and in some quarters the market has a slight tendency to weaken. **Chlorate of Potash,** crystals and granulated, about 3d. per lb.; little interest is shown in offers at this rate. **Caustic Potash,** 88—92%, on spot, about £32. to £33. per ton, in drums; some little business continues here, with prices now fairly steady. **Permanganate of Potash,** commercial quality, 9½d. to 10d. per lb.; this market has improved, and prices are firm at the higher rates mentioned. **Prussiate of Potash,** yellow, about 1s. 2d. to 1s. 2½d. per lb.; the little business coming on the market is keenly competed for; no further fall in prices recorded. **Sulphate of Potash,** 96%, £11. 10s. per ton, ex ship; the position is as reported last week. **Mercury,** about £9. 15s. to £10. per bottle of 75-76lb.; with a continuance of the poor demand, this market has slumped badly, but may recover. **Red Lead,** imported, about £35. 10s. to £36. per ton, c.i.f. London; at these unchanged rates importers find a fair volume of business. **Salammoniac,** dog-tooth crystals, £48. 10s. to £49.; medium, £43. to £44.; fine white crystals, £25. to £26. per ton; somewhat easier conditions obtain in this market; the demand continues slow and limited. **Saltcake,** ground and unground, home trade, about £4. 5s. and £5. 5s. for export, delivered and f.o.b. respectively; British makers' prices are steady at these rates. **Acetate of Soda,** about £25. 10s. per ton, for a few spot parcels offering. **Soda Ash,** 58% light alkali, £7. 12s. 6d. per ton, in bags, carriage paid to destination; British makers quote at about this figure for home trade only; their prices for export vary as to destination. **Soda Crystals,** £5. 5s. per ton, in bags, carriage paid to destination; British makers quoting at this price, for home trade only; dealers are offering at competitive rates, ex wharf or stores. **Caustic Soda,** 70—72%, £18. 10s.; 76—77%, £20. 10s. per ton, in drums, ex wharf shipping port; dealers continue to quote at about these rates, with business still on the small side. British makers' price, for home trade only, are at about £19. to £21. 10s. per ton, in drums, carriage paid; their prices for export vary as to destination. **Bicarbonate of Soda,** £10. 10s. per ton, in bags, carriage paid to destination; British makers quoting at this price for home trade only; dealers are offering at about level figures. **Bichromate of Soda,** home trade, about 4¼d. per lb.; export, slightly more; British makers' prices show no change; business slow. **Cyanide of Soda,** 98—100%, export, about 8¼d. to 9d. per lb.; home trade, about 10½d. per lb.; British makers offering at these prices. **Nitrate of Soda,** 96%, about £13. 7s. 6d. per ton, f.o.r. United Kingdom port; this market keeps very steady. **Nitrite of Soda,** 100%, about £26. 10s. to £27. per ton; this market is unchanged on the week. **Prussiate of Soda,** about 6½d. per lb.; the demand for this article remains slow, and prices quoted on spot are unchanged. **Hyposulphite of Soda,** pea crystals, about £14. 10s. to £15. per ton, in 1cwt. kegs, ex stores; commercial quality, about £9. per ton. **Sodium Sulphide,** 60—62%, solid, £14. to £14. 10s.; ditto, broken, £15. to £15. 5s. per ton, in drums; dealers are offering Continental material at about these figures, with the demand slow. **Sulphate of Copper,** about £26. per ton; Continental material is still offering at cheap rates, with the demand still small. **Tin Crystals,** 1s. 4d. per lb.; this market shows no change on the week. **Tartaric Acid,** B.P., crystals, about 1s. 2½d. per

lb., less 5%; the spot position seems rather doubtful, with the demand still slow and limited; the tendency for the future seems to be towards easier rates. **White Lead,** imported, about £43. to £44. per ton; dealers are quoting at about these figures, with business very limited. **Zinc Oxide,** B.P., about £51.; white seal, about £43.; 99.5%, about £37. 10s. per ton, f.o.r. makers' works; British makers report that prices are inclined to harden.

Pharmaceutical Chemicals.—There has certainly been more inquiry on the market of late, but the majority of the business is still for small lots. Prices are holding up very well, and some advances are recorded. Bromides seem to be a poor feature on spot. **Acetanilid,** crystals and powder, about 1s. 6d. per lb.; some offers on spot might be at lower rates, but the market seems a little firmer. **Acetyl-Salicylic Acid,** B.P., about 3s. 1d. per lb.; prices quoted for spot supplies are firming up to this higher rate, and fair business has been done. **Benzoic Acid,** B.P., about 2s. 6d. per lb.; no interest is shown here; price quoted is nominal. **Diethylbarbituric Acid,** B.P. (barbitone), 18s. per lb.; a sharp drop in the dealers' price is recorded here, with the market dull. **Salicylic Acid,** B.P., 2s. 3d. to 2s. 4d. per lb.; prices have moved to higher levels, and the tone of the market is good; business is fair. **Tannic Acid,** leviss, about 3s. 4d. to 3s. 6d. per lb.; the spot position keeps very steady at these rates. **Amidopyrin,** about 14s. 3d. to 14s. 6d. per lb.; the position of this product on spot keeps very steady at unchanged values. **Ammonium Bromide,** about 7d. per lb.; this is one of the weak features, with spot supplies seemingly ample to meet the rather poor demand. **Benzonaphthol,** about 5s. per lb.; nominal; no movement on the market. **Benzaldehyde 03,** about 3s. per lb.; only small business is recorded, and quoted prices are steady. **Betanaphthol,** resublimed, about 1s. 11d. to 2s. per lb.; dealers quote at about these figures, with little doing at present. **Calcium Lactate,** about 1s. 9d. per lb.; this price governs a much steadier market, with business limited. **Chloral Hydrate,** duty paid, about 4s. per lb.; the demand for this product remains light, with quoted rates well maintained. **Creosote,** B.P., about 2s. 5d. to 2s. 6d. per lb.; a sharp advance in spot offers is recorded in most quarters. **Creosote Carbonate,** about 8s. 6d. per lb.; inquiry remains small here, and dealers are offering at unchanged rates. **Guaiacol Carbonate,** about 8s. 3d. per lb.; this market shows but little sign of life. **Hexamine,** about 3s. 9d. per lb.; a further fall in spot values is recorded, with the market still rather unsteady as quoted. **Hydroquinone,** about 3s. 6d. per lb.; this price seems difficult to obtain on spot. **Methyl Salicylate,** about 2s. 6d. per lb.; the tone has improved here, and slightly higher prices are being asked in some quarters. **Methyl Sulphonal,** about 15s. per lb.; the demand remains very small; dealers' quoted rates are unaltered. **Paraformaldehyde,** 3s. 6d. per lb.; after the recent advances in the price of this article, the market has moved sharply in buyers' favour. **Paraldehyde,** about 1s. 5½d. to 1s. 6d. per lb.; these prices are being quoted, but most sales for fair quantities would possibly be slightly cheaper. **Phenacetin,** about 6s. per lb.; at this level the spot position keeps fairly steady, although business is not brisk. **Phenazone,** about 7s. 6d. per lb.; the quoted rate is fully maintained here, and shows no sign of breaking. **Phenolphthalein,** 6s. 6d. to 6s. 9d. per lb.; the position shows no change, with spot prices firm. **Piperazine,** about 3s. per oz., in kilo. lots; spot offers are made at this price, with little doing. **Potassium Bromide,** crystals and granulated, 6½d. per lb.; the spot position shows no improvement; stocks seem too plentiful, with the demand poor. **Potassium Permanganate,** B.P., 10d. to 10½d. per lb.; at these prices the market seems to be firming up a little. **Potassium Sulphoguaiacolate,** about 5s. 6d. per lb.; there has been very little inquiry on the market. **Salol,** about 2s. 8d. per lb.; the market seems to have steadied up at this cheaper rate. **Sodium Benzoate,** about 2s. 6d. per lb., nominal; still no life in this market. **Sodium Bromide,** B.P., crystals and granular, about 7d. to 7½d. per lb.; offers on spot seem to vary a great deal, and buyers should be able to obtain at low prices for quantities. **Sodium Diethylbarbiturate,** about 18s. 6d. per lb.; a further slight reduction in price is recorded, with the market still dull. **Sodium Salicylate,** powder, about 2s. 5d.; crystals, about 2s. 8d.; flake, about 2s. 11d. per lb.; spot supplies seem rather limited, and prices as quoted appear very steady. **Sulphonal,** about 14s. 6d. per lb., nominal; the market remains idle. **Terpin Hydrate,** about 1s 9d. per lb.; this market keeps very steady, although business is small. **Thymol,** about 15s. per lb.; spot offers are being made at about this figure, with little interest shown.

Coal-tar Products, Intermediates, Etc.—Pitch is now quoted nominal at a slightly advanced figure. In other directions this market has shown a little more life, and prices are being fairly well maintained. Toluol has advanced. **Aniline Oil,** about 9d. to 9¼d. per lb., in drums; quoted rates are unaltered on a quiet market. **Aniline Salt,** about 9¼d. to 10d. per lb., in casks; the market remains dull at unchanged values. **Betanaphthol,** 1s. 1d. to 1s. 2d. per lb.; business remains slow, with values unchanged. **Benzol,** 1s. 4d. per gallon, f.o.r. makers' works, in buyers' packages; this article is now steady, and likely to remain on its present level for some time. **Toluol,** about 2s. per gallon, f.o.r. makers' works, in buyers' packages; a firmer tone is recorded here, with prices moving up sharply. **Xylol,** pure, 2s. 3d.; commercial, 1s. 6d. per gallon, drums extra; dealers are quoting at these unchanged rates on a quiet market. **Naphtha,** about 1s. 4d. per gallon; this product has weakened to still lower rates during the week. **Solvent Naphtha,** 90/160, 1s. 5d. per gallon, drums extra; the quoted rate shows no change, but the market is dull and rather unsteady. **Heavy Solvent Naphtha,** 90/190, 1s. 4d. per gallon, drums extra; prices show no change, with the market quiet and weak. **Special Oil,** for Diesels and motors, 10d. per gallon, barrels free; the market shows no change on the week, and business quiet. **Burning Oil,** crude, No. 3, 8½d.; No. 2, 8d. per gallon, barrels free; quoted rates are the same as last week, with the market steady. **Creosote Oil,** 10d. per gallon, f.o.b.; the dull tone previously reported continues, with the market price fully maintained. **Carbolic Acid,** crystals, about 1s. 2d. per lb., f.o.b.; this price governs a steady but quiet market. **Naphthalene,** £20. per ton; dealers continue to quote at this level; crude, £7. to £13.; crystals, £20.; powder, £17.; balls, £24.; candles, £28.; tablets, £28. per ton, packages free. **Disinfectants,** 3s. 9d. per gallon, barrels free; dealers are quoting at this unaltered rate. **Pyridine,** 20s. per gallon; at this further advanced price the spot position is very firm. **Hexamethylene,** about 3s. 9d. per gallon; spot values have fallen away sharply, but the market seems fairly steady at this lower level. **Pure Methyl Alcohol,** £100. per ton, ex wharf London; importers are showing no signs of making any reduction in their price. **Pitch,** about 140s. per ton, in London; nominal. **Sulphate of Ammonia,** quiet home inquiry at the fixed price of £14. 10s. per ton, delivery over September. This rate is for consumption in the United Kingdom only. Export values are slightly higher, with good inquiry.

LONDON METAL MARKET. Wednesday.

Copper: Standard brands, £64. 17s. 6d. to £65., cash; £65. 8s. 9d. to £65. 10s., three months; electrolytic, £70. 10s. to £70. 15s. **Tin**: Standard, £190. 7s. 6d. to £190. 10s., cash; £191. 7s. 6d. to £191. 12s. 6d., three months; Straits, £193. 17s. 6d.; English, £191. **Lead,** soft foreign, £24. 7s. 6d., prompt; English, £25. 15s.; chemical sheet, 34s. per cwt. for 2-ton lots, delivered. **Spelter,** prompt, £33. 12s. 6d.; hard, £27. 15s. **Antimony,** English regulus, 99%, £28. 5s. to £29. 10s.; special brands, £34. 10s. to £35. **Aluminium,** 98—99%, £115. to £120.; foreign, £110., c.i.f. **Nickel,** £130., delivered; £125. to £130. for export, f.o.b. **Mercury,** £9. **Bismuth,** 10s. **Platinum,** 500s. per oz. **Wolfram,** spot, 12s. 6d. to 12s. 9d. per unit, c.i.f. United Kingdom or Continent. **Zinc Dust,** quotations are as follows: Highest grade English, 90—92%, £47. 10s. per ton, delivered; Beaver brand, 90%, £47. 10s.; American, 92—94%, £47. 10s.; Continental, 85—88%, £45. There is no Australian material on offer, stocks having been cleared.

MANCHESTER CHEMICAL MARKET. Wednesday.

The demand for heavy chemicals continues on the dull side, both on export and home account, and prices generally remain in buyers' favour. For **Caustic Soda,** prices have been reduced for home trade as follows: 76%, £19. 7s. 6d.; 70%, £17. 17s. 6d.; powdered, 77—78%, £22. per ton. **Ammonia Alkali, Bicarbonate of Soda,** and **Soda Crystals** are unchanged. **Bleaching Powder,** softwoods, quiet at £11. 7s. 6d., f.o.r. **Glauber's Salt,** easy at £4., carriage paid. **Chlorates** and **Bichromates** are without alteration. There

is little inquiry for **Copper Sulphate**, and price nominal at £26., f.o.b. American **Sulphur**, firm at £5. 5s. on rails. **Phosphate** and **Commercial Hyposulphite of Soda** are moving off slowly; **Nitrite of Soda**, steady at £26. 10s., ex store. White powdered **Arsenic** is lower at £68., on rails Cornish works. **Yellow Prussiates** have a downward tendency; **Potash** at 1s. 2d., and **Soda** 6d. to 6¼d. per lb. **Carbonate** and **Caustic Potash** are unaltered. Quotations for **Acetic Acid** and **Acetate of Soda** are maintained, and there is fairly good inquiry. Grey and brown **Acetate of Lime** are in short supply, and prices are firm. **Miscible Wood Naphtha**, 6s. 6d. per gallon. **Acetone**, higher at £128. **Lead Salts** are dull, but values without change. **Acetate**, white £41., brown £43.; and **Nitrate**, £42., delivered. Foreign **Litharge**, lower at £35. **Barium Chloride**, quiet at £15. per ton. **Copperas** continues in steady request, and prices show some improvement. **Oxalic Acid**, weak at 6d. per lb. **Permanganate of Potash**, 9¾d. per lb.

SWANSEA MARKET REPORT.

Wednesday.

A little business was done in **Tinplates** for immediate delivery on the basis of £1. 3s. 1½d. per box. **Galvanised Sheets** met with better inquiry, and prices were fairly firm at £18. 7s. 6d. per ton, f.o.b. **Copper** quiet and steady, with prompt at £64. 12s. 6d. per ton, and three months £64. 7s. 6d. **Tin** firmer; prompt £185. 12s. 6d., three months £186. 17s. 6d. **Lead**, steady at £24. per ton, forward; English, £25. 10s. **Spelter** more active, with increased sales at £33. 2s. 6d. per ton prompt, and forward £32. 17s. 6d. **Zinc Sheets**, £36. 17s. 6d. per ton. **Linseed Oil** firm, with raw at £2. 3s. 3d., and boiled £2. 5s. 3d. per cwt. **Cotton-seed oil**, common edible £2. 1s. 3d., and deodorised £2. 4s. 3d. per cwt., net. **Coconut Oil**, dull and nominal. **Olive Oil** quiet at £66. 17s. 6d. per ton, ex ship. **Rape Oil** easier, with best refined at £2. 3s. 3d. per cwt. **Cod Oil**, scarce and nominal. **Palm Oil**, very firm; Lagos, prompt, £33. 12s. 6d.; softs, £33. 12s. 6d. prompt, and £33. 15s. forward; mediums, £33. 15s. 6d.; hards, £34. 2s. 6d. **Copperas**, slow at £2. per ton, delivered. **Arsenic** meets with small trade at £71. 12s. 6d. per ton for white powdered. **Pitch** was rather easier at about £6. 12s. 6d. per ton for best qualities. **Oxalic Acid**, dull at 6¼d. per lb., f.o.r. **Benzol**, in good call at 1s. 4d. per gallon, at ovens. **Sulphate of Ammonia**, quiet but steady, with home-trade prices at £13. 7s. to £14. 10s. **Sulphate of Copper**, dull at £26. 2s. 6d. per ton, less 5%. **Nitrate of Soda** in limited sale, with prompt at £13. 12s. 6d. per ton. **Bone Meal** slow, with Indian, prompt, £9. 2s. 6d. per ton. **Turpentine** steady, with American, prompt, at £3. 14s. 3d. per cwt. **Sulphuric Acid**, in steady demand at £3. 15s. per ton upwards, on rails makers' works. There was a more optimistic feeling on the **Coal** exchange, in the belief that France and Belgium would be wanting larger supplies: Best Admiralty smokeless steam coal £1. 9s. 6d., seconds £1. 8s.; ordinaries, £1. 7s. per ton, all f.o.b. **Anthracite**, best large £2. 9s. 6d., seconds £1. 19s. 6d.; Paris nuts, £3.; all f.o.b., per ton. **Patent Fuel**, rather quiet at £1. 10s. to £1. 14s. per ton, f.o.b. **Cokes** less active; export, £2. 7s. 6d. per ton, f.o.b.; foundry, £2.; and furnace, £1. 10s. per ton, on rails at ovens.

LIVERPOOL CHEMICAL MARKET.

Wednesday.

Business in chemicals of the heavier class for use in the United Kingdom has taken place on a moderate scale, and has continued fairly steady throughout the week. In the export branch a fair trade is being done, and a rather free movement of stocks on foreign account continues. **Bleaching Powder** has had a steady sale, and is £10. to £11. per ton for use in the United Kingdom, and £11. per ton for export. **Calcium Chloride** continues to meet with a very fair inquiry, and is £5. 12s. 6d. per ton. **Caustic Soda** has had a moderate sale for home-trade uses, and has moved somewhat freely on export account; prices are: for use in the U.K., £19. 10s. to £21. 10s. per ton, carriage paid; and for export, £19. 10s. per ton. **Bicarbonate of Soda** has been rather more in request for home-trade uses, and has had a fair shipment on foreign account; it is £10. 10s. per ton, carriage paid, for use in the United Kingdom. **Soda Crystals** have been in quietly steady demand, and are £5. 5s. per ton for home-trade uses. **Nitrate of Soda** has had a moderate sale, and is £13. 5s. to £13. 10s per ton. **Borax** has had a very fair sale, and is £26. 10s. to £27. 10s. for commercial crystals, and £28. for powdered; for higher grades, £31. for crystals and £32. per ton for powdered, carriage paid in the United Kingdom, is quoted. **Saltcake** has been rather more in request, and is £4. 10s. to £5 per ton for the home trade, and £5. to £6. per ton for export. **Bichromate of Soda** has been quiet, and is 4¾d. per lb., c.i.f. to usual ports. **Ammonia Alkali** has had a fair inquiry for use in the United Kingdom, and has been shipped freely on foreign account; it is £7. 12s. 6d. per ton for home-trade uses, and £8. per ton for export. **Hyposulphite of Soda** has again been in rather good demand, and is £10. 10s. to £11. per ton, in 2cwt. bags, for commercial, and £15. to £16. per ton in 1cwt. kegs for photographic. **Sulphide of Soda** has been but little in demand; solid is £15. 10s. per ton, and crystals £9. to £10. per ton. **Chlorate of Soda** has been very quiet, and is 3d. to 3½d. per lb. **Phosphate of Soda** has had a very limited inquiry, and is £15. to £15. 10s. per ton. **Prussiate of Soda** has been in moderate demand, and is 6¾d. to 7d. per lb. **Yellow Prussiate of Potash** has sold more readily, and is 1s. 2¼d. to 1s. 3d. per lb. **Red Prussiate** has been quiet, and is 3s. 6d. per lb. **Carbonate of Potash** has moved but slowly, and is £25. to £32. per ton, according to quality. **Nitrate of Potash** has had a steady and fair sale, and is £33. to £35. per ton for refined. **Chlorate of Potash** has had a moderate inquiry, and is 3½d. to 4d. per lb. **Caustic Potash** has had a very limited sale, and is £32. to £33. per ton. **Permanganate of Potash** has been in quietly steady demand, and is 9¾d. to 10d. per lb. **Bichromate of Potash** has been quiet, and is 5¾d. per lb., c.i.f. to usual ports. **Salammoniac** has been in moderate demand; first quality is £63. per ton, second quality £60., and third £57. **Sulphate of Ammonia** has had a small sale for use in the United Kingdom, but has had a rather large shipment for foreign ports; neutral of 25¾% is £14. 10s. per ton, and ordinary of 25¼% £13. 7s. per ton, for home-trade use. **Carbonate of Ammonia** has had a steady but moderate inquiry, and is 4d. per lb. **Muriate of Ammonia** has been but little called for, and is £32. to £33. per ton. **Magnesia** has had a very fair inquiry; **Carbonate** is £2. 5s. per cwt., and **Sulphate** £5. to £6. per ton. **Alum** has been rather more in request; it is £12. per ton for home-trade uses, and £11. to £11. 10s. per ton for export. **Sulphate of Alumina** has been but little called for; it is £8. to £10. 10s. per ton, according to quality. **Sulphur** has been more in request; flowers are £10. per ton, roll is £8. 10s. per ton, rock £8. to £8. 10s. per ton, and American £5. to £5. 10s. per ton. **Tartaric Acid** has been in very fair request, and is 1s. 2¼d. to 1s. 3d. per lb. **Cream of Tartar** has sold rather freely, and is £4. 10s. to £4. 15s. per cwt. **Boric Acid** has been steadily called for; commercial crystals are £52. per ton, and powdered is £58., £2. per ton extra being charged if in casks. **Citric Acid** has been quieter, and is 1s. 8d. to 1s. 8½d. per lb. **Oxalic Acid** has been very quiet, and is 6d. to 6¼d. per lb. **White Acetate of Lead** has had a limited inquiry, and is £42. to £43. per ton. **Sulphate of Copper** has moved but slowly for home-trade uses or for export; it is £25. 10s. to £26. per ton, less 5%, in casks, f.o.b. at Liverpool. **Arsenic** continues quiet; white powdered is £72. per ton.

WEST OF SCOTLAND CHEMICALS.

Wednesday.

A little more activity has again been noticeable in the Glasgow market during the week, and business, though still of small dimensions, is considered as having a more hopeful tone. The usual day-to-day demand for chemicals on home account is maintained, but inquiries for export are still of a limited character. Prices generally are easier. Quotations, at Glasgow, are as follows:—**Alum**, quiet, and in small demand; prices steady at £12. 5s. for lump, and ground £12. per ton. **Arsenic** continues in short request, and supplies are still very scarce; the quotation is further reduced to £75. per ton, net, on spot. **Barium Chloride** remains very quiet, despite the recent reduction to £15. per ton. **Bleaching Powder** does not show much movement, and the quotation stands at £11. 7s. 6d. **Boric Acid and Borax Crystals** are little sought for; makers' prices for the former stand at £50. per ton, and £27. per ton for the latter. **Borax**, granulated, is on offer at £26. 10s. per ton net, in 2cwt. bags. **Calcium Chloride**, 70—75%, solid, £5. 12s. 6d. per ton. **Citric Acid** is a quieter market, with the price maintained at 1s. 7¼d. per lb., less 5%. **Copper Sulphate** is but little in request at last week's figure of £27. 10s. per ton, less 5%, at Liverpool. **Cream of Tartar** quieter, with smaller

inquiry at the reduced price of £4. 7s. per cwt. for 99%, at Glasgow. **Lead Acetate** is in fair request; brown steady at £41. per ton, net; and white better at £41. 10s. per ton, net. The market for **Magnesium Chloride** is slow, with quiet business at £3. for spot. **Oxalic Acid** is 6¼d. per lb. **Paraffin Wax** experiences a quietly steady trade at 2½d. per lb. **Potash Salts** remain generally steady, with **Bichromate** at 5¾d.; **Chlorate** in request at 4d.; and **Prussiate** rather dull at the lower figure of 1s. 3¼d.; all per lb. at Glasgow. **Salammoniac** indicates only quiet business at £60. and £57. for first and second lump respectively; crystals steady at £48. 10s. per ton. **Saltpetre** is £1. 10s. per cwt., but business is nominal at this reduced figure. **Sodium Bichromate** remains steady, with business on the basis of 4½d. per lb.; **Chlorate** is quieter at 3½d.; while **Prussiate** continues in steady demand at 10½d. per lb. **Bicarbonate of Soda** is in good supply at £9. 15s. per ton, in 2cwt. bags; and £11. 10s. in 1cwt. kegs. **Tartar Emetic,** 43—44%, rather easier, and inclined to be dull at 1s. 1d. **Tartaric Acid** still shows a quiet tendency at 1s. 2¾d. per lb., less 5%, Glasgow.

IMPORTS OF CHEMICAL PRODUCTS

At the Principal Ports of the United Kingdom.

NOTICES.

All communications for the "Chemical Trade Journal and Chemical Engineer" should be addressed and Cheques and Post Office Orders made payable to—

DAVIS BROS., 265, STRAND, LONDON, W.C. 2.

The Terms of Subscription, commencing at any date, to the *Chemical Trade Journal and Chemical Engineer*—payable in advance, including postage—are as follows:—

	United Kingdom.	British Possessions and Foreign Countries.
Yearly (52 numbers)	**19s. 6d.**	..... **24s.**
Half-yearly (26 numbers) ...	**10s. 6d.**	..... **13s.**
Quarterly (13 numbers) ...	**5s. 6d.**	..... **7s.**

Subscribers, particularly those who bind their copies, are requested to renew their subscriptions immediately on receipt of expiry notice, as otherwise delivery will be stopped, and issues between expiry and renewal cannot be supplied.

Our Registered Telegraphic Addresses are:—
"Trepex, Estrand, London." "Expert, Manchester."

Our Telephone Numbers are—
London: 13692, Central. Manchester: 3060, Central.

Our Manchester Address is Barton House, 66, Deansgate.

ADVERTISEMENTS.

DISPLAYED.

Rates upon application. Series may be booked for weekly, fortnightly, or monthly insertions. Contracts arranged either for fixed or varied space. Settlement quarterly. Copy may be altered or changed as frequently as desired.

SMALL.

Rates upon application. Order must be accompanied by remittance (Cheque or Postal Order).

CURRENT TOPICS.

THE WORLD'S RADIUM SUPPLIES.

IT is not generally realised how completely the world's radium position has changed since the discovery in 1913 of new sources of uranium ore in the Belgian Congo, and particularly since the discovery of the Kasolo deposit by the British prospector, Sharp, in 1915. Up to within a year or two ago—for the outbreak of war did not permit extensive work on the Congo deposits till 1919,—by far the greater proportion of the world's radium had been derived from the deposits of Colorado and Utah, which yield about 5 milligrammes of radium per ton, and in all some 160 grammes of radium bromide had been produced. The new Belgian deposits, however, have proved so rich in radio-active constituents (about 150 milligrammes per ton), and comparatively so easy to work, that the American producers have found the competition too severe and have decided to close down their mines for some years to come. The Belgian mineral is worked up at Oolen, near Antwerp, where the largest and most up-to-date plant in the world has been erected and put into full operation within the short space of eighteen months. The method of extraction employed at Oolen does not differ materially from that worked out by Curie and Debierne. Uranium, iron, copper, lead, calcium, and phosphoric acid are eliminated by a series of operations which leave, as the final product, barium chloride containing about one part in 125,000 of radium chloride. The two chlorides are separated by an exceedingly lengthy series of fractional crystallisations, the first sixty of which are effected in enamelled cast-iron pans of continuously decreasing dimensions, and the subsequent fractionations are carried out in the laboratory until some 2 to 3 grammes of highly radio-active product is obtained. The material is then freed from any trace of lead by hydrogen sulphide, the chlorides converted into bromides, and the operation of crystallisation continued until a product containing 95 to 96 per cent. of radium bromide is reached. Six months ago the current price of radium in the world's markets was £20. to £25. per milligramme. At present the Belgian company, the Société Générale Métallurgique, is offering radium in unlimited quantities at £14. per milligramme, and the price can certainly still further be reduced. The Oolen works are now producing 3 grammes of radium per month, and this production can be increased if necessary to 6 grammes, which means a yearly output of 36 to 72

grammes. Cheap and plentiful supplies of radium, which leave a considerable surplus after medical and purely scientific needs have been met, must lead inevitably to new and valuable industrial applications being found for the material, and is is far from impossible that in the domain of organic chemistry at least, radium may be found an effective catalyst for carrying out certain reactions which at present require high pressures and temperatures, under more comfortable conditions.

THE CONTROL OF OUR DYESTUFFS INDUSTRY.

The resignation of Professor Arthur G. Green from his post of Director of Research to the British Dyestuffs Corporation has created considerable consternation, not only amongst those more or less directly connected with the colour-making and colour-using industries, but among the general public as a whole, and has once again focussed attention upon the internal affairs of our largest dyestuff-making establishment. At the present time Professor Green is our greatest tinctorial chemist. Under any circumstances, therefore, his resignation from active participation in the affairs of the Dyestuffs Corporation at a time so critical as the present would have been greatly regretted. When, however, he gives as his considered reasons for resigning his post that he is dissatisfied at the absolute lack of technical knowledge upon the board of directors, and that he is convinced that under present conditions the permanent establishment of a dyestuffs industry in this country is impossible, his resignation presents a still graver aspect. Professor Green, desirous as he is of doing nothing to hinder the future development of the industry, is naturally reluctant at the moment to go into further details of his motives, but it seems logical to assume that his action is dictated not only by the abstract belief that technical men should be included in the directorate, but by concrete knowledge of loss in efficiency that has occurred through the unsympathetic attitude of a purely commercial board of directors to those working on research problems. The present directors, on the other hand, have every confidence in themselves, and state that they rely implicitly upon, and are guided entirely by, the advice of their experts in all technical matters. Theoretically, such a system of control might appear quite satisfactory, but practically it always has, and probably always will prove rather unsatisfactory. Sir William Alexander, at the annual meeting of the British Dyestuffs Corporation in Manchester last month, explained in detail the present policy of the board in regard to research. This policy is to cut down expenses in the direction of the investigation of new products, and to concentrate the activities of the research staff upon reducing the cost of production and perfecting the quality of the large range of colours made at present. The unsatisfactory financial position of the company, and the pressing demand of the colour users for lower-priced products, were given as the reasons for this change of policy. To the average business man such a policy would appear not only justified, but the only logical one. To the technical man possessing an intimate knowledge of the growth of the German dye industry, however, the policy seems fraught with danger and liable to lead to stagnation. The incessant investigation of new products is, in his view, the lifeblood of the dyestuffs industry. Yet it must not be overlooked that comparison between the German pre-war industry and the world-wide dyestuffs industry of to-day is not absolutely straightforward. It is quite possible that had the German dyestuff industry been confronted with financial and economic difficulties of the magnitude that now face the British industry, similar measures would have been adopted. We are of the definite opinion, however, that irrespective of the merits or demerits of the present policy of the directors, the inclusion on the board of men possessing expert technical knowledge of the industry is the only way to secure internal harmony, and thus promote maximum efficiency in our dyestuffs industry.

THE PYRITES AGREEMENT.

Further particulars are now available regarding the agreement between the principal producers of pyrites. This agreement, as we announced at the time, was, after considerable difficulties had been surmounted, actually signed in the middle of July, and has thus been in operation for some six weeks. All the larger producers, such as the Rio Tinto, the Tharsis Company, Mason and Barry, and the Orkla and Huelva mines, are to retain their main customers, within the limits of the sales quota assigned to them. A certain quota is also allowed the smaller producers, such as the Pena Copper Company and the Esperanza Company, and an indemnity of about 3s. per ton is to be accorded those of the smaller producers whose sales have not reached the maximum allowed by their quota. The Saint Gobain and Montecatini establishments, although not actual signatories to the main agreement, have entered into a separate and subsidiary undertaking, whereby they are accorded the sole selling rights in the French and Italian markets. The agreement is to remain in force for five years, after which the question of further extension will be considered and an executive committee is to supervise matters from London. The functions of this committee will be to regularise production, to control sales, and to fix selling prices at a level dictated by the world demand for the pyrites. According to estimates made by the committee, sales should reach two and a half million tons this year, and this figure has been taken as the basis upon which the quotas have been worked out. It will be remembered that a slight rise occurred in the price of pyrites when rumours of an agreement amongst producers were first heard, but no material change in market conditions has since taken place. It is difficult to prophesy the direction of prices during the next month or so, but after all it is only a question of the intensity of the demand. The agreement should lead to greater economy of production amongst the pyrites suppliers, and the interests of consumers will be safeguarded sufficiently by the competition of sulphur.

GYPSUM AND GYPSUM-PRODUCTS.

A SYNOPSIS OF WELL-KNOWN AND LITTLE-KNOWN USES.

By C. Elliott, B.Sc., A.M.I.C.E.

THE mineral gypsum, $CaSO_4.2H_2O$ both in the crude and calcined condition, has many important uses. These are being continually increased and it is the purpose of this article to discuss the most important of them in some detail, to enumerate the minor applications of gypsum and to touch on the possibilities of extending its industrial employment, especially in this country. Unfortunately the comparatively high cost of the mineral and its disadvantages, such as solubility in water and uncertain strength, have prevented a full realisation of the possibilities that lie in its employment in some directions; but there is no doubt that in many ways gypsum products can show advantages over other materials.

In order to give some idea of the size of the industry in various countries, the following figures may be of interest. In the year 1920 the United Kingdom produced from its mines 291,598 metric tons, India 34,091 metric tons, Canada is credited with 389,319 tons, while the American output reached a total of 3,129,142 short tons. South Australia in the same year produced 40,192 long tons, but the only figures available for France are those for 1913 when the production was 1,726,379 metric tons.

Uses of Gypsum in the Cement Industry.

By far the most important use of raw gypsum is as a retarder in Portland cement. Pure cement sets very quickly, actually in a matter of a few minutes, and as this is obviously not desirable except under very special circumstances, it is necessary to add some substance which will retard the set and for this purpose raw or calcined gypsum may be employed. As the retarding effect is due to the sulphur trioxide, calcined gypsum, $CaSO_4\frac{1}{2}H_2O$ which contains about 55.2 per cent. would be preferable to raw gypsum which contains only 46.5 per cent., if it were not for the fact that the price of the former is roughly double that of the crude mineral. If gypsum is employed then, it is added in coarse lumps to the cement clinker as it leaves the kiln and before it is ground; but if plaster is used, it is added to the cement after grinding. Obviously the first method has the advantage that the cement and gypsum are uniformly mixed. The actual amount added varies from 1 to 3 per cent. depending on the setting time desired, and is limited by the specifications adopted as standard by various countries.

Since sulphur trioxide is the active retarding agent, it has been suggested that natural anhydrite, which is always found associated with gypsum, and which is practically valueless, would be suitable since it contains 58.7 per cent. SO_3, but this is very doubtful as the anhydrite is practically insoluble in water. In 1920 no less than 541,901 short tons of gypsum were thus employed in the American Portland cement industry. In connection with the cement industry many patents have been taken out with the idea of using gypsum as a substitute for limestone by removing the sulphur trioxide in various ways, leaving calcium oxide. The SO_3 could then be recovered as a by-product which would be conveyed to lead chambers and converted into sulphuric acid in the usual way. These efforts do not seem to have passed the experimental stage.

Uses in Agriculture.

In the United States the earliest and for many years the principal use of gypsum was as land plaster, but the amount now used annually (107,443 short tons in 1920) is very small relatively to the other purposes for which it is employed. Although its use in this country is not so common as this, yet a fair amount is added to the soil in the hopfields of Kent and Surrey. It must be understood that gypsum does not act as a direct fertiliser. It is not itself a food for plants and, in fact, its application to some soils would be valueless if not actually injurious. Its beneficial effect is realised only if there are certain elements in the soil with which it can react. For example, it accelerates the decomposition of zeolites and acts on the double silicates of magnesia and potash, thus liberating these valuable plant foods. Also should there be any black alkali (Na_2CO_3) or any magnesium carbonate in the soil, the gypsum converts these into sulphates and is itself converted into calcium carbonate which has no injurious effect. Its employment as land plaster is especially favourable in promoting the growth of cloves and other leguminous plants. It is claimed that the perviousness of sandy soil to water can be reduced and non-porous clay soils rendered more porous by the addition of the mineral. Another valuable property is its affinity for water, which is so great that it is of considerable service when starting grass or grain crops since it retains the water just where the roots of the young weak plants require it most.

Crops Saved by Gypsum.

In a hot season gypsum will often save a crop because it absorbs the moisture from the air. In Australia in 1921, the Government carried out experiments with gypsum on light soils in order to endeavour to raise wheat. A dressing of the soil at the rate of one and a half tons of gypsum and 100lb. of superphosphate per acre produced a yield of 27.4 bushels as compared with a yield of 6.5 bushels without the dressing. These experiments were repeated in 1922 and the yields were 9 bushels with no dressing, 15.1 bushels with 100lb. of superphosphate and 25.6 bushels when gypsum was also added.

In a similar connection there may be mentioned the ability of gypsum to absorb the ammonia from manure heaps and stable floors which would otherwise lose this valuable constituent. A small quantity—3 to 4lb. per animal per day—scattered on the floor of a stable or a cowshed will combine with the nitrogen in the manure to form ammonium sulphate according to the equation:

$$(NH_4)_2CO_3 + CaSO_4 = CaCO_3 + (NH_4)_2SO_4.$$

In this form the nitrogen is easily available as a plant food and has the advantage that it is stable in the air, is not washed from the heap by rain, but is retained until the manure is applied to the land. It is claimed that the gypsum also causes the potash and phosphates to be retained in manure, while if the mineral be added to a heap in alternate layers, only a few per cent. of the ammonia will be lost even after five or six months storage. In connection with these remarks it is interesting to notice that in the Badische synthetic-ammonia plant the ammonia made by the fixation of nitrogen extracted from the air is converted into ammonium sulphate according to the equation:

$$2NH_3 + CO_2 + H_2O + CaSO_4 = (NH_4)_2SO_4 + CaCO_3.$$

In chemical fertilisers, gypsum is mixed with superphosphates to bring the percentage of the latter to about 80 per cent., and sometimes partly-calcined material is added to act as a drier and to prevent the development of any mould.

Gypsum in the Paint Trade.

In the paint trade a considerable amount of calcium sulphate is employed in various ways. It is often found in combination with white lead and in some white paints, but owing to its solubility in water (1 part dissolves in 400/500 parts of water) it is used to only a limited extent in paints for exterior work. It finds considerable use in railway paints and in dipping or implement paints to prevent rust. Gypsum is also used as a substratum on which to strike certain organic lakes, notably para reds, while in Venetian reds it is often found to the extent of 50-80 per cent. Thus high class Venetian red may contain 50 per cent. ferric oxide and 50 per cent. calcium sulphate, although in this case the form of sulphate used is that which has been strongly heated and is therefore quite anhydrous and insoluble. Chrome yellow paints of a common class often have the mineral as a tinting agent and Brunswick blues also contain gypsum. The colour of a pure commercial gypsum is a good white, though with more blue in it than barytes but less than in white lead, and it is lighter than either of these pigments, but heavier than china clay or zinc white. As a pigment itself, gypsum is only suitable for use with water as a vehicle, for with oil it loses its opacity and becomes more or less transparent. It is however quite permanent when exposed to light and air and, being neutral in its properties, can be mixed with any other pigment. Gypsum possesses good covering power and in this respect is better than white lead, barytes, zinc white or lead sulphate. Artificial gypsum —*i.e.*, precipitated calcium sulphate is better than the natural variety because it is more amorphous—*i.e.*, less crystalline in structure and has a better body and covering power.

Value in Water for Breweries.

The quality of the water available in the neighbourhood of a brewery often influences the particular type of beer made. Thus the Burton water, which has its origin in the Keuper beds in the district, is very suitable for the manufacture of the pale ales for which the place is famous, this being due to the large amount of calcium sulphate dissolved

in the water which increases the solubility of the albuminous matter in malt. The amount of calcium sulphate present in a typical water from Burton-on-Trent is 78 grains per gallon, the other constituents such as magnesium and calcium carbonate, sodium sulphate, etc., having a total of 55.5 grains per gallon. If the water is too soft and does not contain sufficient sulphate, then gypsum can be added to remedy the defect, care being taken that it is as pure as possible and quite free from marl. A suitable analysis would be as follows:

	Per cent.
Gypsum	98.84
Silica	0.34
Alumina and Iron	0.34
Magnesia	0.08
Alkalies	0.14
Moisture and Organic Matter	0.26
Total	100.00

If the water is too hard, then it can be diluted with a softer water, or the calcium sulphate partly removed by the addition of sodium carbonate. In the manufacture of black beer the water should be soft and contain relatively large amounts of calcium and magnesium carbonate and but little gypsum, while water adapted for mild ales should have large amounts of chlorides and again little gypsum.

Gypsum in Foodstuffs.

The writer has seen it stated that the first grinders of gypsum were the millers and the first calciners were the bakers, so that it appears that they recognised some of its advantages, though possibly the poet Tennyson appreciated the other point of view when he wrote:

> "And chalk and alum and plaster are sold to the poor for bread."

The use of gypsum as an adulterant is not however confined to bread, for it is found in sugar, baking powder, and many other foodstuffs according to the ingenuity of the maker and his regard for the law. Although this use of gypsum is very small and, let us hope, decreasing, yet the presence of the mineral in water has considerable influence in bread making and in excessive quantities it checks the fermentative action of the yeast, this being noticeable in the waters of the great Cheshire plain which come from the new sandstone rocks and in the Burton water just mentioned. Soft alkaline waters possess great extractive powers and they also affect the protein constituents such as gluten and permit its being more readily modified and degraded, whereas hard waters, especially of the gypsum type, retard these actions. Gypsum in common with salt has an antiseptic action. Like sulphates in general, gypsum has a binding effect on flour and it also causes bread, after cutting, to become dry quickly, as may be noticed in the case of exhibition loaves to which it has been added to improve the texture.

Paper Making and Crayons.

In the manufacture of paper it is usual to add to the paper pulp a quantity of a cheap mineral loading agent or filler to make the paper more suitable for the particular purpose for which it is intended. Thus kaolin or china clay is used for newsprint and for any other papers of a low grade, but for the better qualities of writing paper gypsum is usually though not exclusively employed. The addition of a filler closes up the pores, gives a smoother surface and increases its absorbent powers for printing and other inks. It also gives it an improved surface for calendering and increases the opacity of the paper.

The common blackboard or school crayon, commonly known as chalk, is made of finely-pulverised crude gypsum. To this are added certain ingredients such as a suitable binder and, where coloured crayons are required, a small amount of a pigment of the necessary colour. After thorough mixing of the gypsum and the added materials, these are pressed into shape in suitable moulds by the application of pressure.

Miscellaneous Uses of Gypsum and Anhydrite.

Gypsum is employed in the cotton and lace trades to give a finish to cheap classes of goods; to some extent in the tin trade for polishing tin plates, although in this case an impure gypsum containing a large amount of marl is preferred; as an ingredient of Paris green and other insecticides; as a flux to galena concentrate in the Carmichael-Bradford blast-roasting process of reducing lead ore in the United States; as a smelter in New South Wales; as a flux in the concentration of lead-copper matte in reverberatory furnaces in Germany; as a source of the sulphur necessary for collecting the nickel into a matte in the smelting of certain ores of that metal in New Caledonia, in which case it also acts as a base to counteract and slag the siliceous gangue; for the dusting of coal mines as made compulsory by law and for many other purposes.

In the unground state large quantities of fine-grained semi-transparent or translucent gypsum or alabaster are used by sculptors for statuary and for ornamental and useful purposes such as electric light shades. The alabaster reredos by Gilbert Scott in Ely Cathedral is an excellent and beautiful example and it can also be seen as ornamental work in Manchester, Buxton and many other places. Another variety of gypsum called selenite occurs in nature in transparent, flaky pieces and has the property of cleavage so highly developed that it may be split into very thin flakes which caused its use in earlier days as a substitute for our present-day window glass. Selenite is also used to a limited extent in optical apparatus and for making examinations with polarised light.

On account of its solubility in water gypsum has not found any extensive application for external work, but in a few places in the arid regions of the south-western parts of the United States and in other parts of the globe where similar conditions hold, gypsum has been quarried in blocks and used for the walls of buildings, and under favourable climatic conditions such walls may remain secure for many years. Occasionally in the same localities gypsum has been employed as a road material.

The mammillated masses of gypsum that often occur at the top of the seam or in swallow holes where they have been attacked by water, are sometimes sold as rockery or grotto stone, especially the red or pink varieties. Anhydrite, which is always found associated with gypsum and satinspar, which is an aggregate of long fibrous crystals of gypsum, is also used for this purpose, while crushed spar for walks and screened spar for pebble-dashing find some sale. Anhydrite is always a nuisance to the owners of a gypsum deposit and is difficult to get rid of. In addition to the uses already mentioned, it has been employed occasionally as a road material.

The Uses of Plaster.

When gypsum is calcined the water of crystallisation is driven off in two stages,* usually called the first and second boil respectively, the first where plaster consisting mainly of $CaSO_4.\frac{1}{2}H_2O$ is obtained, which is known as plaster of Paris or first settle plaster, the second where the material is mostly anhydrous calcium sulphate and is termed second settle plaster. Since second settle plaster reverts to first settle on keeping, through picking up moisture from the air, it is only made for immediate use at the works and is manufactured in relatively small proportions. In the following enumeration of the uses of plaster, it is understood that the word plaster refers to first settle plaster only unless otherwise stated. In discussing the various uses to which gypsum plasters can be put it is clearer to adopt two main classifications, one where the material is used with the addition of water only and the other where other material is added to it before the water is applied.

Plaster in Pottery Moulds.

Large quantities of plaster are used annually by the manufacturers of pottery and architectural terra cotta in making moulds for their designs, a purpose for which it is very suitable for not only is there ample strength combined with light weight but the moulds are easily made and inexpensive. In addition the porosity of the set mould permits proper absorption of the moisture from the clay and its subsequent evaporation, whilst the surface of the ware is not exposed to dangerous draughts. It will also be recalled that plaster, in setting with water, expands owing to a change in its crystalline form, and it is due to this expansion that the moulds can take an impression of the smallest details of the original model. These details will then be reproduced faithfully in the pottery and ware made in these moulds. A plaster suitable for pottery moulds is usually very finely ground, probably all passing through a 100 mesh sieve, but there is not the same need for a fine material for terra cotta moulds.

Plaster in Plate Glass Manufacture.

Manufacturers of plate glass use large amounts of plaster on which to bed the glass during grinding and polishing. The rough glass plates are placed on large circular tables—up to 24 feet in diameter—which have been covered

* See also the article on "Plaster-of-Paris Technology," by Mr. C. Elliott, in *The Chemical Trade Journal and Chemical Engineer* June 15, 1923, page 725.

previously with a bed of plaster on which the glass settles. When the plaster has set it makes a firm support and relieves the glass from all strains. As soon as one face of the glass has been polished, the plaster is broken away from the edges, the plate removed and the table cleaned. A fresh layer of plaster is then spread out and the plate replaced with its polished side down, and the other side is ground and polished. For the first bed the old set plaster is often reground and recalcined, so that when mixed with fresh plaster it can be used for the rough side, but when the polished face is downwards only fresh plaster is used on account of the danger of scratches. The plaster used for this purpose must be very finely ground and free from grit.

An Invaluable Aid in Surgery and Dentistry.

Plaster is used by surgeons for casts around broken limbs, a purpose for which it is very valuable for it is plastic, sets quickly and gives good support to the injured member and is also a non-conductor of heat and unaffected by moisture. There is no equally-available and suitable substitute, but the idea is by no means novel since in earlier days the Persians immersed people whom they disliked up to the neck in a mass of wet plaster which, when expanding during setting, slowly crushed the unfortunates to death.

In orthopedic surgery, open-mesh bandages of various widths are passed through a tray containing dry plaster which is caught up by the meshes. The bandages are then rolled up very tightly and when required for use are immersed in water for a couple of minutes and then unrolled and wound round the injured part of the patient, forming when set a very strong splint.

The amount of plaster used in dentistry is not relatively very large, but it is important. In the United States in 1920, 1,721 short tons were used in this way out of a total of 1,578,360 short tons of plaster produced and considering the small quantities that are used at a time, this is a considerable total. The plaster is used in the construction of models of teeth and contiguous parts, as an investing material in the process of vulcanising and for taking impressions of the mouth. For the last purpose an extremely fine-grained material to which an accelerator has been added is preferred, since the qualities demanded in such work are reproduction of fine details and a quick set. The fines from the last screenings of reground calcined gypsum are suitable for this purpose. Plaster used for investing work and for dental casts and models is not so finely ground and it sets slower, but is harder when set. Impression plaster is not so strong, and this is really advantageous as it fractures easily and facilitates the withdrawal of the impression from the undercut spaces.

Methods of Reducing the Expansion of Plaster.

While the expansion which occurs on setting is advantageous and useful for obtaining good detail work, yet the errors due to it are important and very considerable research has been carried out on the subject. It has been found that an acqueous solution of potassium sulphate and especially sodium potassium tartrate (Rochelle salt) reduces the setting time and also the expansion. Thus a solution of 40 grains of the tartrate in 1½ ounces of water used with 2½ ounces of plaster, reduces the set by half and the expansion to one-fiftieth of that of pure plaster.

Plaster in Engineering Pattern Making.

In some copper refineries plaster is used to bind the flue dust and concentrates by mixing it with these and putting the whole into sacks which become solid when the plaster has set. The solid blocks can then be removed without difficulty to the furnaces for the recovery of the valuable constituents originally carried away in the flue dust.

For certain special castings and for casting Babbitt metal, plaster is used fairly extensively for the moulds, as it is porous and resistant to fusion while, mixed with a pure grade of wheat flour, the material is known as Corine flour and is employed to dust moulds for metal castings.

An increasing outlet for plaster is found in the construction of patterns in foundries, a purpose for which it can show considerable advantages, such as simplicity, cheapness and speed of construction. Thus the cost of some patterns in the best quality yellow pine usually used is twice that of those made of plaster, and one of the chief disadvantages of the former is liability to warp which need not be feared with plaster. In the case of circular designs, the plaster patterns may be finished direct by strickling with templates and by suitable methods much irregularly shaped work can also be made by templates. In other cases it may be necessary to cut or shave the patterns or to make additions, operations to which the material particularly lends itself. When the pattern is of large size, the setting time is increased by the addition of a suitable retarder, usually lime, and in the case of large blocks coke may be used as a centre on which only a thin layer of plaster need be run, so that the patterns are lighter and cheaper. Projections, corners, and other weak parts that might get broken, are often strengthened by white metal pieces, which can be either nailed on or placed in the mould before the plaster is poured.

Miscellaneous Uses of Pure Plaster.

A considerable amount of plaster is used in the manufacture of small statues, busts, etc., which find a ready sale and are inexpensive, and it is invaluable for making negative moulds for replicas of ancient statues and pieces of architectural ornament, for the reproduction of models of relief maps, and scientific models originally made in clay or any other plastic material. It is also used for the statues or maps themselves which are made from the negative moulds, all the minute details of the original being faithfully reproduced.

Amongst other minor uses may be mentioned the use of the material for the heads of matches, between the hollow walls of safes as a fire resistant; for the blocks on which hats are made; in taxidermy, for finishing the surface over which skin is drawn; in paleontology, for supplying missing parts and for imbedding fragile fossils for transportation; in mouldings, cornices and artistic designs, such as relief decorations on walls and ceilings; as a mould for rubber stamps into which the plastic rubber is poured and for other various purposes.

Gypsum Plaster Boards and Tiles.

Plaster with the addition of hair, wood fibre, sand and retarders is employed in buildings for walls and ceilings, for the exterior surfaces of temporary work such as exhibitions, for the setting up of marble construction and glazed tile walls and for making decorative artificial stones. The amount consumed in these ways is very great, but a description of and discussion on its use in this way would be more suitable for a journal catering for the building trade. A brief description of gypsum plaster boards and tiles and of reinforced gypsum will, however, be given, as these are of definite interest to the engineers of chemical works.

Gypsum plaster boards are thin sheets of plaster with a fibrous binding material—such as tough paper or wool felt—which gives the necessary strength and toughness. The simplest boards have one layer of plaster between two layers of felt, but 2 or 3 layers of plaster between 3 or 4 layers of felt are also common and all are made automatically and continuously by ingenious machinery. These boards are remarkably strong and much superior to lath and plaster. They are light, very markedly fire resistant, excellent non-conductors of heat and can be cut with the greatest of ease. Gypsum tiles are simply large blocks of set plaster with a suitable filler, such as wood fibre, added to decrease still further the weight and to give additional strength. Both plaster boards and tiles are made in this country and are extensively used. One of the principal uses of second settle plaster in America is in the manufacture of these tiles, a purpose for which it is very suitable.

Reinforced Gypsum as a Constructional Material.

Gypsum is weak in tension and shear but strong in compression, and when it is suitably reinforced it is an excellent material for roofs and floors. Its employment for these purposes, in fact, has reached very great proportions in North America where some firms have many acres of gypsum construction. The work may be either done *in situ* or precast at the mill and dropped in place and in both methods, one of the greatest advantages is the speed of erection. With poured-in-place construction a gang of men can easily lay 7,000 sq. ft. in one working day and it is very remarkable that an hour after pouring in the plaster, full load can be applied and all the wood form-work dropped, which contrasts very strongly with the weeks that must elapse before concrete can be put into service. Since gypsum as used in floor construction is less than half the weight of concrete, it is obvious that the supporting structure can be made much lighter and naturally the foundations needed are also less.

An important point is the complete absence of condensation where gypsum roofs and floors are employed, provided of course that there is reasonable ventilation. Being an excellent non-conductor of heat it is possible to have a bitter

frost outside a building and a hot steamy atmosphere inside without any trace of moisture or condensation on the inside surface of the roof. For the same reason extremes of temperature have little effect on the temperature of the interior of a building, which conduces to the greater comfort of the workers and therefore to increased output. If for any reason it is desired to cut through a gypsum floor or roof, the operation is carried out with the greatest of ease and speed, whereas most of us have experienced the great difficulties of cutting concrete and the long time required. When reinforced gypsum slabs are made at the mill then second settle plaster is often employed because it is stronger when set and also denser and harder.

One of the great advantages of gypsum construction is the resistance that it offers to heat, and in this respect it occupies a high position in the list of materials suitable for this purpose.* In a chemical works, it is very valuable for buildings where inflammable liquids are stored and in many cases a lower fire insurance rate can be obtained when gypsum is used in the construction, while its actual fire record is magnificent.

Gypsum is, of course, by no means a universal material. It has certain uses for which it is pre-eminent, others for which it gives every satisfaction, but in other cases is quite unsuitable. There is no doubt, however, that the uses of gypsum products will be extended considerably as time elapses, and with a more general appreciation of its properties, realisation of its advantages and improvements in its manufacture and subsequent technical treatment.

THE LIQUEFACTION OF COAL.

THE BERGIUS HYDROGENATION PROCESS.

By David Brownlie, B.Sc., M.I.Mech.E.

IN this article it is proposed to give a short account of the remarkable work now being undertaken in connection with the so-called "liquefaction" of coal, that is, the action of hydrogen on coal at enormous pressures whereby the volatile matter of the coal absorbs large amounts of hydrogen, and the complex chemical reactions result in the greater portion of the coal being converted into a thick liquid almost identical with crude petroleum. The extraction of oil from coal is, in my opinion, bound to be a large-scale commercial proposition in the very near future. For one thing the known reserves of coal in the world are enormous, sufficient at least for the next 4,000 years at our present consumption of, say, 1,400,000,000 tons per annum, allowing for a steady increase in this figure, and it is obvious further deposits remain to be discovered. Low temperature carbonisation of coal will in general give us 20-25 gallons of oils per ton of coal, in addition to sulphate of ammonia. It is true that so far low-temperature carbonisation is not a commercial proposition, but well over 30 processes are being investigated, and in many cases the work has been in progress for 10 years past, and a very small dividing line indeed now separates several of these processes from complete success.

The Preparation of "Artificial Coal."

The idea, however, of utilising the volatile matter present in coal to the extent of an average of, say, 25-30 per cent. by direct combination with hydrogen, and what may be described as increasing the amount of such material instead of decomposing part of it by carbonisation, so as to obtain the rest in a liquid condition, is a remarkable one. The pioneer in this field is undoubtedly Dr. F. Bergius, of Mannheim, in Germany, who about 10 years ago, commenced research work in connection with the constitution of coal. The general method adopted by Bergius, following on the work of earlier investigators such as Stein and Klason, was to endeavour to prepare an artificial coal substance. During this work Bergius discovered that if cellulose, peat, or similar woody material from which coal has been derived, is heated in autoclaves at very high temperatures and pressures, such as 1,500lb. and 640° F., after about 12 hours such cellulosic material is converted into a black substance somewhat resembling coal, and containing 84 per cent. carbon, 5 per cent. hydrogen, and 11 per cent. oxygen, a large amount of carbon dioxide having been given off in the process. This artificial coal, it will be noted, contains as high a percentage of carbon as very many existing coals, an achievement which the earlier investigators could never manage.

The Use of Enormous Pressures.

Bergius also discovered that in closed autoclaves the chemical reactions that took place were strongly exothermic, and that the large amount of heat evolved resulted in a considerable portion of the material being partially destroyed and converted into coke, but there was no method of controlling the sudden rise in temperature. This difficulty was finally surmounted by placing the autoclaves in water. The heat is then readily absorbed and no coke is formed. Bergius himself, however, encountered the greatest difficulty when endeavouring to raise the percentage of carbon much over 85 per cent., and finally was only able to obtain a product, containing 88 per cent. of carbon by the use of enormous and dangerous pressures, in some cases as high as 5,000 atmospheres (75,000lb. to the square inch). Under these conditions methane begins to be evolved, and we are therefore within the region of the true coal substance, since methane is a regular constituent of the coal seams.

The First Hydrogenation Experiments of Bergius.

It was whilst carrying out this fascinating work that Bergius discovered that his artificial coal substance containing 85-88 per cent. of carbon would combine with hydrogen, and that at very high temperatures and pressures in the autoclaves, such as, for example, 850° F. and 3,000lb. per square inch, a large volume of hydrogen was absorbed and the whole of the solid material converted into a thick liquid, which apparently had the same general complex composition as crude petroleum. Bergius then applied this discovery to natural coal, and found that the latter, in a pulverised condition at high temperatures and pressures, would readily absorb a large amount of hydrogen, and be nearly all converted into a liquid material with a very high hydrogen content. It may be stated that this process of hydrogenation is now being applied on a commercial scale in Germany to oils of every description, that is to say, the direct conversion of heavy petroleum and other oils of comparatively little value into much lighter and lower boiling-point oils. This work is being undertaken by the Company with which Dr. Bergius is associated at Rheinau, near Mannheim.

Plant Details for the Hydrogenation of Heavy Oils.

A given quality of heavy oil is first examined experimentally in the laboratory so as to find out the best method of dealing with it on a large scale. For this work a small 5-litre steel autoclave is used, in which is placed a weighed amount of oil, and hydrogen is then pumped in at the required pressure, after which the autoclave is heated. It is then slowly revolved whilst being heated by means of powerful gas jets, the operation being carried out in heavy reinforced concrete chambers. The pressure developed is enormous, often as high as 3,000lb. per square inch, and because of the dangerous nature of the work all the controls are electrical and operated from a considerable distance. So far, however, no accidents have occurred. The autoclave is then allowed to cool down and the liquid product examined and analysed, so that in this way the best conditions as regards temperature and the amount of hydrogen necessary are determined experimentally before proceeding with the work on a large scale.

The latter plant is on essentially the same lines, and consists of very heavy steel autoclaves with a capacity of about one ton of oil per 24 hours. The construction of these autoclaves seems to be to a large extent kept secret, and many points are not clear, but they are about 30 feet long, and of 3 feet internal diameter, having a replaceable steel liner and internal mechanical agitator. The heating is carried out in the most ingenious manner by passing continuously between the inner and outer lining of the autoclave, a current of very high pressure nitrogen gas heated to the necessary temperature. The oil is pumped into the autoclave by means of high pressure force pumps, on the way being heated in coils by the exit nitrogen from the autoclaves, and the action seems to be continuous in the sense that the hydrogen under pressure is passed in continuously, the lighter hydrocarbons formed from the oil being passed away at once to a dephlegmating apparatus, which is also under pressure, whilst the heavy liquid residue in the autoclaves is at the same time withdrawn continuously.

The complete installation is stated to have a capacity of 50 tons of oil per 24 hours, and as in the case of the laboratory trials, the whole equipment is worked behind enormous

* See footnote on page 246.

reinforced concrete chambers controlled from a distance, and here again no accident has yet occurred.

Practical Difficulties in Coal Liquefaction.

The application of this method, however, to the commercial manufacture of products like crude petroleum direct from the coal itself is a matter of extraordinary difficulty. In the first place coal, no matter how finely pulverised, is still a solid, and therefore it is impossible to get the same intimate contact between the hydrogen and the material to be hydrogenated. Consequently a much longer contact is necessary, say 12 hours, in place of the usual short period for a liquid, so that the output is seriously reduced. Another difficulty, as already indicated, is that the reaction is exothermic, and therefore it is extremely difficult to control the temperature and prevent a large amount of coked material being formed. However, there seems to be no doubt that the genius of investigators who are busy with the problem in various parts of the world will get over this trouble, and one method which is being investigated by Dr. Bergius is to suspend finely pulverised coal in heavy oil as a medium and circulate this through the autoclaves instead of ordinary oil.

Of course a very great deal depends on the composition of the coal itself, that is to say, the percentage of volatile matter present. If chemically-pure carbon in the form of charcoal is submitted to the action of hydrogen under enormous pressures there is no reaction whatever, and it is found also that it is practically impossible to obtain a chemical reaction at any known pressure between hydrogen and highly anthracitic coals, that is to say, qualities containing over 85 per cent. carbon, calculated on the ash-free basis, or very roughly, over 90 per cent. carbon in the coal. Ordinary coal contains on an average 25-35 per cent. volatile matter, and when this is treated at varying pressures from 600-3,000lb., and say 750° F. with hydrogen, a considerable portion of the coal is converted into a thick and complicated liquid, which seems to be almost identical with crude petroleum, and which in the same way can be separated by fractionation into an enormous range of different chemical compounds. The nature of the reaction occurring is at present being investigated, but it would appear that all the oxygen in the coal is converted into phenols, the nitrogen into ammonia or ammonium compounds, and the sulphur into sulphuretted hydrogen.

Recent Suggestions Involving the Use of Catalysts.

Already there are rumours of catalysts being applied to the hydrogenation of coal, in particular of the method of H. Magnus, of Freiburg, Baden. In this, pulverised coal is stated to be passed continuously through retorts in the presence of hydrogen, which is caused to combine at a quite moderate pressure and temperature by means of two separate catalysts, and is then converted into the liquid product. No details, however, are yet available, and this may be an exaggeration, but it shows the tendency, and there are further rumours of another process on somewhat similar lines which is now at work in Czecho-Slovakia.

Another possibility of causing coal to combine with hydrogen under moderate conditions of temperature and pressure is represented by the use of hydrogen in a nascent condition. The German chemists, H. Fischer and H. Schräder, use pulverised coal or lignite with sodium formate prepared in the ordinary way from formic acid. When sodium formate is heated at a temperature of about 680° F. it decomposes, forming sodium oxalate and liberating free hydrogen, which at the moment is in the nascent condition. It is stated that if one part of powdered sodium formate and four parts of pulverised lignite are intimately mixed and heated for three hours at 750° F. in a current of steam at ordinary pressures, the nascent hydrogen liberated by the decomposition of the sodium formate results in about 25 per cent. of the lignite being converted into a liquid product. If the same operation is carried out at high pressures very nearly 50 per cent. of the lignite is converted into liquid.

Finally much experimental work is also being undertaken in connection with the heating of powdered bituminous coal at about 450° F. for 10 hours in a strongly alkaline solution in the presence of compressed air, using iron or manganese salts as a catalysts. Under this treatment the coal substance is almost entirely decomposed by oxidation, a large amount of gas being formed, together with a complicated resinous material something like turpentine, and a considerable amount of complex fatty organic acids which dissolve in the alkali present.
